**SUGGESTED SOLUTION**

**Problem 1**

1. Since the given expression for  $\delta_l$  does not depend on energy, the scattering amplitude

$$f(\vartheta) = \frac{1}{k} \sum_{l=0}^{\infty} (2l+1) e^{i\delta_l} \sin \delta_l P_l(\cos \vartheta) \quad (1)$$

will be proportional to  $k^{-1}$ , and the differential cross section will be inversely proportional to the energy:

$$\frac{d\sigma}{d\Omega} = |f^2| \propto 1/k^2 \propto 1/E. \quad (2)$$

2. For small  $g$ , we have

$$\delta_l = \frac{\pi}{2} \left( l + \frac{1}{2} - \sqrt{\left( l + \frac{1}{2} \right)^2 + g} \right) \simeq -\frac{\pi g/2}{2l+1}. \quad (3)$$

The phase shifts are negative, as expected for a positive potential as discussed in the lectures. Inserting this phase-shift into the scattering amplitude and using that  $|\delta_l| \ll 1$ , we get:

$$f(\vartheta) = \frac{1}{k} \sum_{l=0}^{\infty} (2l+1) \delta_l P_l(\cos \vartheta) = -\frac{\pi g}{2k} \sum_{l=0}^{\infty} P_l(\cos \vartheta). \quad (4)$$

With the help of the generating function for Legendre polynomials

$$\sum_{l=0}^{\infty} s^l P_l(\cos \vartheta) = (1 - 2s \cos \vartheta + s^2)^{-1/2}, \quad (5)$$

we get with  $s = 1$  that

$$\sum_{l=0}^{\infty} P_l(\cos \vartheta) = \frac{1}{2 \sin(\vartheta/2)}. \quad (6)$$

The scattering amplitude then becomes

$$f(\vartheta) = -\frac{\pi g}{4k \sin(\vartheta/2)} \quad (7)$$

and scattering cross section

$$\frac{d\sigma}{d\Omega} = \frac{\pi^2 g^2}{16k^2 \sin^2(\vartheta/2)}. \quad (8)$$

3. The Born approximation for the scattering cross section is  $d\sigma/d\Omega = |f|^2$  with

$$f(\vartheta) = -\frac{m}{2\pi\hbar^2} \int V(r)e^{-iq\cdot r} dr = -\frac{2m}{\hbar^2 q} \int_0^\infty V(r) \sin(qr) r dr \quad (9)$$

when integration over the angles is done. Here,  $q = 2k \sin(\vartheta/2)$ . For our potential we get

$$f(\vartheta) = -\frac{g}{q} \int_0^\infty \frac{\sin \xi}{\xi} d\xi = -\frac{g\pi}{2q}. \quad (10)$$

We have introduced  $qr = \xi$  and used that the last integral is  $\pi/2$ . Inserting  $q$ , the scattering amplitude in the Born approximation becomes

$$f(\vartheta) = -\frac{\pi g}{4k \sin(\vartheta/2)}. \quad (11)$$

This is precisely the same expression as the one we got from the scattering phases.

4. The radial equation for this potential is

$$-\frac{\hbar^2}{2m} \frac{d^2 u}{dr^2} + \left[ \frac{\hbar^2 l(l+1)}{2mr^2} + \frac{\hbar^2 g}{2mr^2} \right] u = Eu. \quad (12)$$

This can be rewritten as

$$-\frac{d^2 u}{dr^2} + \frac{\tilde{l}(\tilde{l}+1)}{r^2} u - k^2 u = 0. \quad (13)$$

Here,  $E = \hbar^2 k^2 / 2m$  and

$$\tilde{l}(\tilde{l}+1) = l(l+1) + g. \quad (14)$$

The rewritten equation now looks like a radial equation without any potential, with the asymptotic solution

$$R_l(r) \propto \frac{\sin(kr - \tilde{l}\pi/2)}{r}. \quad (15)$$

The solution of the Schrodinger equation has the following form at large  $r$ :

$$R_l(r) \propto \frac{\sin(kr - l\pi/2 + \delta_l)}{r} \quad (16)$$

which is used to define the scattering phase shift  $\delta_l$ . Comparing the last two equations gives

$$\delta_l = \pi(l - \tilde{l})/2. \quad (17)$$

The only remaining task is to solve the second order equation Eq. (14) with respect to  $\tilde{l}$ :

$$\tilde{l} = -\frac{1}{2} \pm \sqrt{(l+1/2)^2 + g}. \quad (18)$$

We must use the + sign in front of the square root to ensure that  $\tilde{l} > 0$  (and when  $g = 0$  we must have  $\tilde{l} = l$ ). Inserted, we get

$$\delta_l = \frac{\pi}{2} \left( l + \frac{1}{2} - \sqrt{(l + \frac{1}{2})^2 + g} \right). \quad (19)$$

**Problem 2**

a) The wavefunction must be defined for  $r = 0$ , so only the sin term is allowed ( $C = 0$ ). Moreover, the wavefunction is continuous at  $r = a$ , whereas its derivative is not continuous due to the  $\delta$ -function potential. Specifically, consider the radial equation for  $u$  (recall that  $\psi = R(r) = u(r)/r$ ):

$$-\frac{\hbar^2}{2m} \frac{d^2 u}{dr^2} + \alpha \delta(x) u = E u. \quad (20)$$

Integrating across an infinitesimal interval centered at  $r = a$ , i.e. from  $r = a - \varepsilon$  to  $r = a + \varepsilon$  and taking  $\lim_{\varepsilon \rightarrow 0}$ , we get

$$\lim_{\varepsilon \rightarrow 0} \frac{du}{dr} \Big|_{a-\varepsilon}^{a+\varepsilon} = \frac{2m\alpha}{\hbar^2} u(a). \quad (21)$$

Using now the continuity and derivative boundary condition to get rid of the remaining unknown constants  $A$  and  $B$ , we obtain the equation

$$c + ika_0 y = (\beta s/a + kc)(a_0 y/s + 1/k), \quad (22)$$

where we defined the quantities

$$\beta = 2m\alpha a/\hbar^2, \quad s = \sin(ka), \quad c = \cos(ka), \quad y = e^{ika}. \quad (23)$$

Solving for  $a_0$  and taking the limit  $ka \ll 1$  gives

$$a_0 \simeq -\frac{\beta a}{1 + \beta}. \quad (24)$$

b) The total scattering cross section is

$$\sigma = \int d\Omega |f|^2 = \int d\Omega |a_0|^2 = 4\pi \frac{\beta^2 a^2}{(1 + \beta)^2}. \quad (25)$$

As  $\alpha \rightarrow \infty$ , we get  $\beta \rightarrow \infty$ , which in turn makes  $\sigma \rightarrow 4\pi a^2$ . This is the same result as the quantum mechanical total scattering cross section for low-energy scattering on a hard sphere potential of radius  $a$ .
