Abstract: This paper deals with a hybrid actuator composed by a piezo and a hydraulic part and with a cascade PID-PD control structure for camless engine motor applications. The idea is to use the advantages of both, the high precision of the piezo and the force of the hydraulic part. In fact, piezoelectric actuators (PEAs) are commonly used for precision positionings, despite PEAs present nonlinearities, such as hysteresis, saturations, and creep. In the control problem such nonlinearities must be taken into account. In this paper the Preisach dynamic model with the above mentioned nonlinearities is considered together with a cascade PID-PD controller which is realized through sliding surfaces. Simulations with real data are shown.

Keywords: PID controllers, Lyapunov’s approach, piezo actuators

1. INTRODUCTION

In the last few years, variable engine valve control in camless systems has attracted a lot of attention because of its ability to reduce pumping losses (work required to draw air into the cylinder under part-load operation) and to increase torque performance over a wider range than conventional spark-ignition engine. Variable valve timing also allows control of internal exhaust gas recirculation, thus improving fuel economy and reducing NOx emissions. Besides mechanical and hydraulic variable valvetrain options, electromagnetic valve actuators have been reported in the past. Theoretically, electromagnetic valve actuators offer the highest potential to improve fuel economy due to their control flexibility. In real applications, however, the electromagnetic valve actuators developed so far mostly suffer from high power consumption and other control problems. This kind of actuators presents a high value of inductance which can generate some problems of the electromagnetic compatibility with the environment. Therefore, innovative and alternative concepts are required to reduce the losses and drawbacks while keeping a high actuator dynamic which is characterized by high value of velocity and generated force. The idea which this paper presents is to use hybrid actuator composed by a piezo and a hydraulic part in order to take advantages of both, the high precision and velocity of the piezo and the force of the hydraulic part. Moreover, piezo actuators present in general less problems of electromagnetic compatibility due to the quasi absence of the inductance effects. The main advantage of PA is nanometer scale, high stiffness, and fast response. However, since PA has nonlinear property which is called hysteresis effect, it leads to inaccuracy in positioning control with high precise performance. PID regulators are very often applied in industrial application. Recently, variable engine valve control has attracted a lot of attention because of its ability to improve fuel economy, reduce NOx emissions and to increase torque performance over a wider range than a conventional spark-ignition engine. In combination with microprocessor control, key functions of the motor management can be efficiently controlled by such mechatronic actuators. For moving distances between 5 and 8 mm, however, there are other actuator types with different advantages. In [P. Mercorelli and S. Liu and K. Lehmann] we presented an adaptive PID controller design for the valve actuator control based on flatness property and interval polynomials. The objective of this paper is to show:

- A model of the a hybrid actuator
- A PID-PD cascade regulator in order to avoid poor dynamic performance

The paper is organized with the following sections. Section 2 is devoted to the model description. In Section 3 an algorithm is shown to derive the control laws. The paper ends with Section 4 in which simulation results of the proposed valve using real data are presented. After that the conclusions.

2. MODELING OF THE PIEZO HYDRAULIC ACTUATOR

The proposed nonlinearity model for PEA is quite similar to these presented in [A. Adriaens et al. 2000] and in [Y.-C. Yu and M.-K. Lee 2005]. It is basically constructed from a sandwich model as shown in Fig. 1, which is based on the following hypothesis. According to the proposed
sandwich model, a PEA is constituted like a three layer sandwich. The middle layer is the effective piezo layer (P-layer), and the two outside layers connected to the electrodes are known in the literature as interfacing layers (I-layers). The P-layer is the layer that has the ordinary characteristics of piezo effects but without the nonlinearities of hysteresis and creep so that its behavior can be modeled by an equivalent linear circuitry. In contrast, the I-layers do not contribute any piezo effect; they are just part of the circuit connecting P-layer to the electrodes in series. In [Y.-C. Yu and M.-K. Lee 2005] it is hypothesized that each of the I-layers can be equivalently represented by a capacitor and a resistor connected together in parallel. Together with the equivalent circuitry for P-layer, Fig. 2 shows the equivalent circuit for a PEA with the I-layer nonlinearities of hysteresis and creep, in which two I-layers are combined together as $C_a$ and $R_a$. The I-layer capacitor, $C_a$, is an ordinary capacitor, "which might be varied slightly with some factors, but here it would be assumed constant first for simplicity. The I-layer resistor, $R_a$, however, is really an extraordinary one with significant nonlinearity. The resistance is either fairly large, say $R_a > 10^6 \, \Omega$, when the voltage $\|V_a\| < V_h$, or is fairly small, say $R_a < 1000$, when $\|V_a\| > V_h$. In [Y.-C. Yu and M.-K. Lee 2005], the threshold voltage, $V_h$, is defined as the hysteresis voltage of a PEA. The authors in [Y.-C. Yu and M.-K. Lee 2005] given this definition due to the observation that there is a significant difference and an abrupt change in resistance across this threshold voltage and it is this resistance difference and change across $V_h$ that introduces the nonlinearities of hysteresis and creep in a PEA. The hysteresis effect could be seen as a function of input $V_{in}(t)$ and output $y(t)$ as follows: $H(y(t), V_{in}(t))$, see Fig. 3. According to this model, if $V_h = 0$, then the hysteresis will disappear, and if $R_a = \infty$ when $\|V_a\| < V_h$, then the creep will also disappear. Based on this proposed sandwich model and the equivalent circuitry as shown in Fig. 2, we can further derive the state model as follows:

$$
\dot{V}_a(t) = -\left(\frac{1}{R_a} + \frac{1}{R_0}\right) \frac{V_a(t)}{C_a} - \frac{V_z(t)}{C_aR_o} + \frac{V_{in}(t)}{C_aR_o},
$$

$$
\dot{V}_z(t) = \frac{Q_b}{C_z} + \frac{1}{C_z}\left(-\frac{V_a(t)}{R_o} - \frac{V_z(t)}{R_o} + \frac{V_{in}(t)}{R_o}\right),
$$

where $Q_b = D_yF_z(t)$ is the “back electric charge force” (back-ecf) in a PEA, see [Y.-C. Yu and M.-K. Lee 2005]. According to [Y.-C. Yu and M.-K. Lee 2005] and the notation of Fig. 4, it is possible to write

$$
F_z(t) = M_p/3\ddot{x}(t) + D_x\dot{x}(t) + K_x(x(t)) + K_{xx}(x(t)).
$$

$K$ and $D$ are the elasticity and the friction constant of the spring which is antagonist to the piezo effect and it is incorporated in the PEA. $C_z$ is the total capacitance of the PEA and $R_o$ is the contact resistance. For further details on this model see [Y.-C. Yu and M.-K. Lee 2005].

Considering the whole system described in Fig. 4 with the assumptions of incompressibility of the oil, the whole mechanical system can be represented by a spring mass structure as shown in the conceptual schema of Fig. 4. In this system the following notation is adopted: $K_x$ is the elasticity constant factors of the PEA. In the technical literature, factor $D_xK_x = T_{cm}$ is known with the name “transformer ratio” and states the most important characteristic of the electromechanical transducer. $M_p/3$ is, in our case, the moving mass of the piezo structure which is a fraction of whole piezo mass, $MSK$ is the sum of the mass of the piston with the oil and the moving actuator and $M_{em}$ is the mass of the oil. It is possible to notice that the moving mass of the piezo structure is just a fraction of the whole piezo mass. The value of this fraction is given by the constructor of the piezo device and it is determined by experimental measurements. $K_{SK}$ and $D_{SK}$ are the characteristics of the antagonist spring to the mechanical servo valve, see Fig. 4. $D_{oil}$ is the friction constant of the oil. Moreover, according to [Y.-C. Yu and M.-K. Lee 2005], motion $x_p(t)$ of diagram in Fig. 3 is

$$
x_p(t) = D_pV_z(t).
$$

According to diagram of Fig. 2, it is possible to write as follows:

$$
V_z = V_{in}(t) - R_0i(t) - H(x_p(t), V_{in}(t)),
$$

where $R_0$ is the connection resistance and $i(t)$ is the input current as shown in Fig. 2. $H(x_p(t), V_{in}(t))$ is the function which describes the hysteresis effect mentioned above and shown in the simulation of Fig. 3. Considering the whole system described in Fig. 4, the electrical and mechanical systems described in Figs. 2, 3 and 4 can be represented by the following mathematical expressions:
Fig. 3. Simulated Hysteresis curve of the piezo part of the actuator: $H(x_p(t), V_{in}(t))$

\[
\frac{M_p}{3} \ddot{x}(t) + M_{SK} \ddot{x}_{SK}(t) + Kx(t) + D\dot{x}(t) + K_{SK}x_{SK}(t) + D_{SK} \ddot{x}_{SK}(t) + D_{oil} \ddot{x}_{SK}(t) + K_x x(t) - \Delta x_p(V_{in}(t)) = 0, \tag{6}
\]

where $\Delta x_p(t)$ represents the interval function of $x_p(t)$ as shown in Fig. 3 which, according to equation (4), can be expressed as

\[
\Delta x_p(t) = D_x \Delta V_z(t), \tag{7}
\]

Finally, using equations (5) and (7),

\[
K_z \Delta x_p(t) = K_z D_x (V_{in}(t) - R_0 y(t) - H(\Delta x_p(t), V_{in}(t))), \tag{8}
\]

which represents the interval force generated by the piezo device. Equation (6) can be expressed in the following way:

\[
\frac{M_p}{3} \ddot{x}(t) + M_{SK} \ddot{x}_{SK}(t) + Kx(t) + D\dot{x}(t) + K_{SK}x_{SK}(t) + D_{SK} \ddot{x}_{SK}(t) + D_{oil} \ddot{x}_{SK}(t) + K_x x(t) = K_z \Delta x_p(V_{in}(t)). \tag{9}
\]

It is to be noticed that the following relationship holds:

\[
x_{SK}(t) = W x(t), \tag{10}
\]

where W is the position ratio above defined and it states the incompressibility of the oil in the conic chamber. The following equation completes the dynamic of the considered system:

\[
M_v y(t) + D_{oil} y(t) = F(x_{SK}(t), y(t)) - F_d(t). \tag{11}
\]

According to Fig. 4, $x(t)$ is the position of the piezo actuator, $x_{SK}(t)$ is the position of the mechanical servo actuator, $y(t)$ represents the position of the valve. Function $F(x_{SK}(t), y(t))$ represents the force exerted by the pump on surface S of the armature of the moving valve, see Fig 4. Moreover,

\[
F(x_{SK}(t), y(t)) = (p_A(t) - p_B(t)) S, \tag{12}
\]

where $p_A(t)$ and $p_B(t)$ are the pressure in the two oil chambers separated by the armature of the valve. In [H. Murrenhoff] pressure $p_A(t)$ and $p_B(t)$ are nonlinear functions of the mechanical servo valve position $y(t)$. The linearization of this function at each desired position $y_d(t)$ will be considered later. $F_d(t)$ is the combustion back pressure in terms of force. According to Fig. 3 in which

\[
\Delta x_p(V_{in}(t)) = [-a \ a] + bV_{in}(t), \tag{13}
\]

with $a \in \mathbb{R}$ and $b \in \mathbb{R}$ two positive constants are indicated. In particular,

\[
\Delta x_p(V_{in}(t)) = -a + bV_{in}(t), \tag{14}
\]

and

\[
\Delta x_p(V_{in}(t)) = a + bV_{in}(t). \tag{15}
\]

Considering this notation, the system represented in (6) can be split into the following two systems:

a) \[
\frac{M_p}{3} \ddot{x}(t) + M_{SK} \ddot{x}_{SK}(t) + Kx(t) + D\dot{x}(t) + K_{SK}x_{SK}(t) + D_{SK} \ddot{x}_{SK}(t) + D_{oil} \ddot{x}_{SK}(t) + K_x x(t) = \Delta x_p(V_{in}(t)), \tag{16}
\]

b) \[
\frac{M_p}{3} \ddot{x}(t) + M_{SK} \ddot{x}_{SK}(t) + Kx(t) + D\dot{x}(t) + K_{SK}x_{SK}(t) + D_{SK} \ddot{x}_{SK}(t) + D_{oil} \ddot{x}_{SK}(t) + K_x x(t) = \overline{\Delta x_p(V_{in}(t))}, \tag{17}
\]

3. A PID-PD CONTROLLER AS TWO SLIDING MODE SURFACES

Figure 3 shows the proposed control structure. It is possible to see how a feedforward structure is present in order to achieve a regulation around the desired trajectory. An internal PD structure and an external PID structure complete the whole control scheme to guarantee the robustness.
Thus the desired piezo trajectories. Equation (22) becomes as
\[ G(x) = \left[ \begin{array}{c}
  x_1(t) \\
  x_2(t) 
\end{array} \right] = \left[ \begin{array}{c}
  x_1(t) - x_1(t) \\
  x_2(t) - x_2(t) 
\end{array} \right], \]
and (19) can be represented as follows:
\[ \dot{x}_1(t) = f(x(t), H(y(t), V_{in}(t))) + BV_{in}(t), \]
where it is considered that \( V_{in}(t) = V_z(t) \),
\[ f(x(t), H(y(t), V_{in}(t))) = \left[ \begin{array}{c}
  x_2(t) \\
  -Dx_2(t) - (K + K_x + K_{SK}W)x_1(t) + 3K_s bV_{in}(t) 
\end{array} \right], \]
and \( B = \left[ \begin{array}{c}
  M_z/3 + M_{SK}W \\
  3M_z b + (-1)^q a 
\end{array} \right] \). The following PD controller is defined:
\[ K(t) = G(x_d(t) - x(t)), \]
where \( G = [P_t, D_t] \), and \( x_d(t) \) represents the vector of the desired piezo trajectories. Equation (22) becomes as follows:
\[ K_i(t) = [P_t, D_t] \left[ \begin{array}{c}
  x_{1d}(t) - x_1(t) \\
  x_{2d}(t) - x_2(t) 
\end{array} \right], \]
thus
\[ K_i(t) = P_t(x_{1d}(t) - x_1(t)) + D_t(x_{2d}(t) - x_2(t)), \]
\[ P_t \text{ and } D_t \text{ are the internal P and the intern D parameters of the PD controller. If the following Lyapunov function is defined:} \]
\[ V(K_i) = \frac{K_i^2(t)}{2}, \]
then it follows that:
\[ \dot{V}(K_i) = K_i(t) \dot{K}_i(t). \]
In order to find the stability of the solution \( s(t) = 0 \), it is possible to choose the following function:
\[ \dot{V}(K_i) = -\eta K_i^2(t), \]
with \( \eta > 0 \). Comparing (26) with (27), the following relationship is obtained:
\[ K_i(t) \dot{K}_i(t) = -\eta K_i^2(t), \]
and finally
\[ K_i(t) (\dot{K}_i(t) + \eta K_i(t)) = 0. \]
The no trivial solution follows from the condition
\[ \dot{K}_i(t) + \eta K_i(t) = 0. \]
From (22) it follows:
\[ \dot{K}_i(t) = G(x_d(t) - x(t)) = Gx_d(t) - Gx(t). \]
The main idea is to find a \( u_{eq}(t) \), an equivalent input, and after that a \( V_{in}(t) \), such that \( \dot{x}(t) = x_d(t) \). For that, from (20) it follows that:
\[ \dot{x}(t) = x_d(t) = f(x_d(t), H) + BV_{in}(t), \]
and from (31) the following relationship is obtained:
\[ \dot{K}_i(t) = G\dot{x}_d(t) - Gf(x_d(t), H) - GBV_{in}(t) = GB(u_{eq}(t) - V_{in}(t)), \]
where \( u_{eq}(t) \) is the equivalent input which, in our case, assumes the following expression:
\[ u_{eq}(t) = (GB)^{-1}G(\dot{x}_d(t) - f(x_d(t), H)). \]
After inserting (33) in (30) the following relationship is obtained:
\[ GB(u_{eq}(t) - V_{in}(t)) + \eta K_i(t) = 0, \]
and in particular
\[ V_{in}(t) = u_{eq}(t) + (GB)^{-1} \eta K_i(t). \]
Normality it is a difficult job to calculate \( u_{eq}(t) \). If equation (33) is rewritten in a discrete form using explicit Euler approximation, then it follows:
\[ K_i((k + 1)T_s) - K_i(kT_s) = GB(u_{eq}(kT_s) - V_{in}(kT_s)). \]
If equation (36) is also rewritten in a discrete form, then
\[ V_{in}(kT_s) = u_{eq}(kT_s) + (GB)^{-1} \eta K_i(kT_s). \]
Equation (37) can be also rewritten as
\[ u_{eq}(kT_s) = V_{in}(kT_s) + (GB)^{-1} K_i((k + 1)T_s) - K_i(kT_s). \]
Equation (39) can be estimated to one-step backward in the following way:
\[ u_{eq}((k - 1)T_s) = V_{in}((k - 1)T_s) + (GB)^{-1} K_i(kT_s) - K_i((k - 1)T_s). \]
Because of function \( u_{eq}(t) \) is a continuous one, we can write
\[ u_{eq}(kT_s) \approx u_{eq}((k - 1)T_s). \]
Considering equation (41), then equation (40) becomes
\[
ueq(kT_s) = V_{in}((k-1)T_s) + \left( GB \right)^{-1} \frac{K_i(kT_s) - K_i((k-1)T_s)}{T_s}.
\]
Inserting (42) into (38)
\[
V_{in}(kT_s) = V_{in}((k-1)T_s) + \left( GB \right)^{-1} \left( \eta K_d(kT_s) + \frac{K_i(kT_s) - K_i((k-1)T_s)}{T_s} \right),
\]
and finally
\[
V_{in}(kT_s) = V_{in}((k-1)T_s) + \left( GBT_s \right)^{-1} \left( \eta T_s K_d(kT_s) + K_i(kT_s) - K_i((k-1)T_s) \right).
\]

3.2 External PID controller

If the following external PID is defined
\[
s_e(t) = [P_c \hspace{1em} D_c \hspace{1em} I_c] \begin{bmatrix} x_{1ed}(t) - x_{1l}(t) \\ x_{2ed}(t) - x_{2l}(t) \\ (x_{1d}(t) - x_1(t))dt \end{bmatrix},
\]
where \( x_{ed}(t) \) represents the vector of the desired valve trajectories. Then after similar calculation the following PID structure is calculated:
\[
V_{in}(kT_s) = V_{in}((k-1)T_s) + (HLT_s)^{-1} \left( \eta T_s K_d(kT_s) + K_c(kT_s) - K_c((k-1)T_s) \right).
\]
The following notation is used: \( G = [P_c \hspace{1em} D_c \hspace{1em} I_c] \) and
\[
H = \begin{bmatrix} 0 \\ -F(x_{SKa}(t))y_{a}(k)/M_v \end{bmatrix},
\]
where \( c_{xSKa}(k) \in \mathbb{R} \) and \( c_{ya}(k) \in \mathbb{R} \) are the constants which come from the linearization of \( F(x_{SK}(t), y(t)) \) at each time.

4. SIMULATIONS RESULTS

The control law of equation (44) is tested using the model described in section 2. Figure 6 shows the final result concerning the tracking of a desired position of an exhaust valve with 8000 rpm. Figure 7 shows the final result concerning the tracking of a desired velocity of an exhaust valve with 8000 rpm. Figure 8 shows the profile of the simulated force on the piezo part of the proposed actuator.

But, the force acting directly on the valve at the opening time has a pick value equal to 700 N circa and it is reduced to a few newtons acting on the piezo part thanks to the decoupling structure of the hybrid actuator. This is one of the greatest advantages of these hybrid actuators. The model of a such kind of disturbance is obtained as an exponent function of the position of the valve. The digital controller is set to work with a sampling time equal to \( 20 \times 10^{-6} \) s, according to the specifications of the Digital Signal Processor which we are intended to test the system with.

**Remark 1.** It is to remark that, equation (44) states that the control law does not depend on the dynamics of the system model. The control law depends for the internal PD controller just on the moving mass and on product \( K_dD_x \) (transformer ratio). All these parameters are always well known in a piezoelectric actuator. Product \( K_dD_x \) depends on the temperature, the piezoelectric actuator is equipped with a temperature sensor which activates an air cooling system. Concerning to external PID controller the control law depends on the moving mass and on the pressures of the two oil chambers, and on the valve surface.

5. CONCLUSIONS AND FUTURE OBJECTIVES

5.1 Conclusions

This paper deals with a hybrid actuator composed by a piezo and a hydraulic part and its control structure for camless engine motor applications. The idea is to use the
advantages of both, the high precision of the piezo and the force of the hydraulic part. In the control problem nonlinearities such as hysteresis, saturations, and creep are taken into account. Simulations with real data of motor and of a piezo actuator are shown.

5.2 Future Works

Future works include an adaptive PID-PD control structure and measurements on an experimental setup. Some refined models of the whole structure are already under consideration. In particular, in the presented paper it is assumed that the oil of the hydraulic part is incompressible. This assumption should be removed and the pressure of the oil should be considered as a further state variable which the system can be described with.
