**Abstract**—In this paper, we study the finite horizon $H_\infty$ fixed-lag smoothing problem for linear descriptor systems. The key approach applied for deriving the $H_\infty$ fixed-lag smoother is the re-organization innovation analysis in Krein space. Under the Krein space, the $H_\infty$ fixed-lag smoothing is converted into an $H_2$ estimation problem for the system with current and delayed measurements. By using innovation re-organization approach, the $H_2$ estimation with delayed measurements is transformed into a problem of delay-free measurements and thus a simple solution to $H_\infty$ smoothing is given.

I. INTRODUCTION

The state estimation for linear descriptor systems has received much attention in the last few years (see [1], [2], [3], [4], [5] and references therein). As is well known, there are mainly two approaches to the linear estimation. One is the linear minimum variance which is termed as $H_2$ estimation. The other is the infinite-horizon $H_\infty$ performance index which involves state augmentation, which leads very much computational cost. As for the normal systems [8], the $H_\infty$ fixed-lag smoothing for descriptor systems is a very complicated problem and remains challenging. There have been a considerable amount of researches on the problem of fixed-lag smoothing for normal systems (see [9], [10], [6], [11]).

The purpose of the present paper is to present a simple method for the finite horizon $H_\infty$ fixed-lag smoothing problem for the descriptor system. Firstly, the $H_\infty$ fixed-lag smoothing problem is converted into $H_2$ estimation for the descriptor system with current and time delayed observations in Krein space. Secondly, we solve the $H_2$ estimation problem with measurement delays by applying re-organized innovation approach.

The following symbols are used throughout this paper. $\delta_{ij}$ is Kronecker delta function and $T$(superscript) denotes the transpose, $k_1 \triangleq k - l$.

**Notation 1:** Whenever the Krein space elements [12] and the Euclidean space elements satisfy the same set of constraints, we shall denote them by the same letters with the former identified by bold faces and the latter by normal faces.

II. PROBLEM STATEMENT

Consider a linear time-invariant system described by the following discrete-time model:

$$Mx(k+1) = \Phi x(k) + \Gamma u(k)$$  \hspace{1cm} (1)

$$y(k) = Hx(k) + v(k)$$  \hspace{1cm} (2)

$$z(k) = Lx(k)$$  \hspace{1cm} (3)

where $x(k) \in \mathbb{R}^n$, $y(k) \in \mathbb{R}^m$, $z(k) \in \mathbb{R}^p$, $u(k) \in \mathbb{R}^r$ and $v(k) \in \mathbb{R}^m$ represent the state, measurement output, the signal to be estimated, input noise, measurement noise, respectively. The initial state $x(0)$ may depend on $u(0)$ as well as a finite number of future values of the input noise $u(k)$, due to the non-causality of the system. It is assumed that the input and measurement noises are bounded deterministic signals.

**Assumption 1:** The system (1) is regular, i.e., exists $s$ such that $\det(sM - \Phi) \neq 0$.

Under Assumption 1, there exist two nonsingular matrices $P_1$ and $Q_1$ such that

$$Q_1MP_1 = \begin{bmatrix} I_{n_1} & 0 \\ 0 & M_1 \end{bmatrix}, \quad Q_1\Phi P_1 = \begin{bmatrix} \Phi_1 & 0 \\ 0 & I_{n_2} \end{bmatrix}$$  \hspace{1cm} (4)

By using innovation re-organization approach, the $H_2$ estimation with delayed measurements is transformed into a problem of delay-free measurements and thus a simple solution to $H_\infty$ smoothing is given.
where \( n_1 + n_2 = n \), \( M_1 \) is a nilpotent matrix with index \( \lambda_0 \), i.e., \( M_1^{n_0} = 0, M_1^{n_0 - 1} \neq 0 \). Then system (1)–(3) is restricted system equivalent (RSE) to the following system.

\[
\begin{align*}
x_1(k+1) &= \Phi_1 x_1(k) + \Gamma_1 u(k), \quad x_1(0) \\
M_1 x_2(k+1) &= x_2(k) + \Gamma_2 u(k) \\
y(k) &= H_1 x_1(k) + H_2 x_2(k) + v(k) \\
z(k) &= L_1 x_1(k) + L_2 x_2(k)
\end{align*}
\]

where \( x_1(k) \in \mathbb{R}^{n_1} \), \( x_2(k) \in \mathbb{R}^{n_2} \), and \( \begin{bmatrix} x_1(k) \\ x_2(k) \end{bmatrix} \).

From (6), we have

\[
x_2(k) = -\Gamma_2 u(k) - M_1 \Gamma_2 u(k+1) - \cdots - M_1^{n_0 - 1} \Gamma_2 u(k + \lambda_0 - 1) \tag{9}
\]

It can be shown that the present state \( x_2(k) \) depends on the future input noises \( u(k), \ldots, u(k + \lambda_0 - 1) \), which implies the non-causality of the descriptor system. In fact, a difference between discrete-time descriptor systems and normal ones is that descriptor systems do not always have solutions for any initial condition \( x(0) \). This point can be easily seen from (9). And in equation (9), let \( k = 0 \),

\[
x(0) = P_1 \begin{bmatrix} x_1(0) \\ \vdots \\ x_{\lambda_0 - 1}(0) \end{bmatrix} - \sum_{i=0}^{\lambda_0 - 1} M_1^i \Gamma_2 u(i)
\]

where \( x_1(0) \) is the initial value of (5). This gives

\[
\begin{bmatrix} 0 & I \end{bmatrix} P_1^{-1} x(0) = -\sum_{i=0}^{\lambda_0 - 1} M_1^i \Gamma_2 u(i) \tag{10}
\]

which is the admissible initial condition satisfied by the initial state \( x(0) \). Denote the set of all admissible initial values of the state \( x(0) \):

\[
I_0 = \{ x \mid x \in \mathbb{R}^{n_1}, \begin{bmatrix} 0 & I \end{bmatrix} P_1^{-1} x(0) = -\sum_{i=0}^{\lambda_0 - 1} M_1^i \Gamma_2 u(i) \}
\]

Then the \( H_{\infty} \) fixed-lag smoothing problem of the descriptor systems can be formulated as:

**Problem 1:** Given a scalar \( \gamma > 0 \), an integer \( l > 0 \) and the observations \( \{ y(i) \}_{i=0}^k \), find an estimate \( \hat{z}(k_i | k) \) of \( z(k_i) \), if exist, such that the following inequality is satisfied

\[
\sup_{(x_0, u, v) \neq 0} \frac{\sum_{k=0}^{N} |z(k_i | k) - z(k_i)|^2}{\|x_1(0)\|_{\Pi_1^{-1}} + \sum_{k=0}^{N+\lambda_0 - 1} u^T(k) u(k) + \sum_{k=0}^{N} v^T(k) v(k)} < \gamma^2
\]

\[
\|x_1(0)\|_{\Pi_1^{-1}} + \sum_{k=0}^{N+\lambda_0 - 1} u^T(k) u(k) + \sum_{k=0}^{N} v^T(k) v(k)
\]

\[
\gamma^2 \left( \|x_1(0)\|_{\Pi_1^{-1}} + \sum_{k=0}^{N+\lambda_0 - 1} u^T(k) u(k) + \sum_{k=0}^{N} v^T(k) v(k) \right)
\]

where \( \|x_1(0)\|_{\Pi_1^{-1}} = x_1^T(0) \Pi_1^{-1} x_1(0) \), and \( \lambda_0 \) is the nilpotent index. \( x_1(0) \) is as in (5) and \( \Pi_1 \) is a given positive definite matrix which reflects the relative uncertainty of the initial state \( x_1(0) \) to the input and measurement noises.

**III. Preliminary**

Recall [13], we define that

\[
J_{l,N} \triangleq x_1^T(0) \Pi_1^{-1} x_1(0) + \sum_{k=0}^{N+\lambda_0 - 1} u^T(k) u(k) + \sum_{k=0}^{N} v^T(k) v(k) - \gamma^2 \sum_{k=0}^{N} v^T(k) v(k)
\]

where \( v_z(k) = \hat{z}(k_i | k) - L z(k_i), k_i = k - l \) and \( v_z(k) = 0, k < l \). Then the \( H_{\infty} \) estimation problem is equivalent to that \( J_{l,N}(x_1(0), u^{N+\lambda_0}, y^N) \) has a minimum over \( \{ x_1(0), u^{N+\lambda_0} \} \) and the estimator is such that the minimum is positive [14], [7]. Further, equation (12) can be rewritten as

\[
J_{l,N} = \begin{bmatrix} x_1(0) \\ u^{N+\lambda_0} \\ v^N \end{bmatrix}^T \begin{bmatrix} \Pi_1 & 0 & 0 \\ 0 & R_{u^{N+\lambda_0}} & 0 \\ 0 & 0 & R_{v^N} \end{bmatrix}^{-1} \begin{bmatrix} x_1(0) \\ u^{N+\lambda_0} \\ v^N \end{bmatrix}
\]

where

\[
u^{N+\lambda_0} = \text{col}\{ u(0), u(1), \ldots, u(N + \lambda_0 - 1) \}\]

\[
R^{N+\lambda_0} = \Pi_1 \oplus \cdots \oplus \Pi_2, Q_u = I_f
\]

and

\[
v^N = \text{col}\{ v_s(0), v_s(1), \ldots, v_s(N) \}\]

\[
v_s(k) = \begin{bmatrix} v(k), 0 \leq k < l \\ v(k_l), k \geq l \end{bmatrix}, k \geq l
\]

Furthermore, putting together (2), (3) and (13) we have

\[
y_s(k) = \begin{bmatrix} y(k), 0 \leq k < l \\ y(k_l), k \geq l \end{bmatrix}, k \geq l
\]

\[
H z(k) + v_s(k), 0 \leq k < l
\]

\[
= \begin{bmatrix} H \quad 0 \\ 0 \quad L \end{bmatrix} \begin{bmatrix} x(k) \\ x(k_l) \end{bmatrix} + v_s(k), k \geq l
\]

It follows that

\[
\begin{bmatrix} x_1(0) \\ u^{N+\lambda_0} \\ y^N \end{bmatrix} = \begin{bmatrix} \Psi \end{bmatrix} \begin{bmatrix} x_1(0) \\ u^{N+\lambda_0} \\ v^N \end{bmatrix}
\]

\[
\Psi = \begin{bmatrix} I_n & 0 & 0 \\ 0 & I_{l_{(N+1)}} & 0 \\ 0 & \Psi_1 & \Psi_0 \end{bmatrix}
\]

where

\[
y^N = \text{col}\{ y_s(0), \ldots, y_s(N) \}\]
and $\Psi$ is invertible. Thus, it is easy to know that (see also [7])

$$J_{l,N} = \begin{bmatrix} x_1(0) \\ u_{N+\lambda_0}^T \\ y_s^N \end{bmatrix}^T \begin{bmatrix} \Pi_1 & 0 & 0 \\ 0 & R_u^{N+\lambda_0} & 0 \\ 0 & 0 & R_{v_s}^N \end{bmatrix}^{-1} \begin{bmatrix} x_1(0) \\ u_{N+\lambda_0}^T \\ y_s^N \end{bmatrix}$$

(22)

On the other hand, based on the state space model (1), (2) and (13), the following stochastic descriptor system is introduced

$$\begin{align*}
Mx(k+1) &= \Phi x(k) + \Gamma u(k) \\
y(k) &= H x(k) + v(k) \\
\tilde{z}(k | k) &= L x(k) + v_z(k)
\end{align*}$$

(23) \hspace{1cm} (24) \hspace{1cm} (25)

where $u(k), v(k)$ and $v_z(k)$, in bold faces, are mutually uncorrelated white noises, $\langle u(k), u(j) \rangle = Q_u \delta_{kj}$, $\langle v(k), v(j) \rangle = Q_v \delta_{kj}$, and $\langle v_z(k), v_z(j) \rangle = Q_{v_z} \delta_{kj}$, while

$$Q_u = I_r, Q_v = I_m, Q_{v_z} = -\gamma^2 I_p$$

(26)

It is easy to know that $J_{l,N}$ in (22) can be rewritten as

$$J_{l,N} = \begin{bmatrix} x_1(0) \\ u_{N+\lambda_0}^T \\ y_s^N \end{bmatrix}^T \begin{bmatrix} \begin{bmatrix} x_1(0) \\ u_{N+\lambda_0}^T \\ y_s^N \end{bmatrix} \\ \begin{bmatrix} x_1(0) \\ u_{N+\lambda_0}^T \\ y_s^N \end{bmatrix} \end{bmatrix}^{-1} \begin{bmatrix} x_1(0) \\ u_{N+\lambda_0}^T \\ y_s^N \end{bmatrix}$$

where $x_1(0), u_{N+\lambda_0}, y_s^N$ in bold faces are from Krein space (23)-(25) and have the same forms as (14), (21). Since the covariance of $v_z(k)$ is negative, $\tilde{z}(k_l | k)$ is regarded as one ‘fictitious’ white noise at time $k$. Now we recall the discussion [14], it is easy to know that the $H_\infty$ fixed-lag smoother $\tilde{z}(k_l | k)$ that is to be sought in this paper is in fact an $H_2$ filtering problem for the associated system with current and delayed measurements as (23)-(25).

IV. $H_\infty$ Fixed-Lag Smoothing for Descriptor Systems

From [15], it is easy to know that the descriptor system (23)-(25) is RSE to the following Krein-space stochastic system

$$\begin{align*}
\tilde{x}(k+1) &= \tilde{\Phi} \tilde{x}(k) + \tilde{\Gamma} \tilde{u}(k) \\
y(k) &= \tilde{H} \tilde{x}(k) + \nu(k) \\
\tilde{z}(k_l | k) &= \tilde{L} \tilde{x}(k_l) + \nu_z(k)
\end{align*}$$

(27) \hspace{1cm} (28) \hspace{1cm} (29)

where

$$\begin{align*}
\tilde{u}(k) &= u(k + \lambda_0 - 1) \\
\tilde{x}(k) &= \begin{bmatrix} x_1^T(k) \\ x_2^T(k) \\ x_3^T(k) \end{bmatrix}^T \\
\tilde{x}_3(k) &= \begin{bmatrix} u^T(k) \\ u^T(k+1) \cdots \ u^T(k + \lambda_0) \end{bmatrix}^T \\
\tilde{\Phi} &= \begin{bmatrix} \Phi_1 & 0 & \Phi_2 \\ 0 & 0 & \Phi_3 \\ 0 & 0 & \Phi_4 \end{bmatrix}
\end{align*}$$

(30) \hspace{1cm} (31) \hspace{1cm} (32) \hspace{1cm} (33)

$\Phi_1$ is defined in (4) and

$$\begin{align*}
\Phi_2 &= \begin{bmatrix} \Gamma_1 & 0 & \cdots & 0 \\ 0 & -\Gamma_2 & \cdots & -\Gamma_3 \end{bmatrix} \in \mathbb{R}^{n \times (\lambda_0+1)} \\
\Phi_3 &= \begin{bmatrix} 0 & \cdots & 0 \\ 0 & \cdots & 0 \end{bmatrix} \in \mathbb{R}^{r \times (\lambda_0+1)} \\
\Phi_4 &= \begin{bmatrix} 0 & \cdots & 0 \\ 0 & \cdots & 0 \end{bmatrix} \in \mathbb{R}^{r \times (\lambda_0+1)}
\end{align*}$$

and

$$\tilde{L} \tilde{x}(k) = \tilde{L} \tilde{x}(k) = \begin{bmatrix} \begin{bmatrix} x_1(k) \\ x_2(k) \end{bmatrix} \end{bmatrix}$$

(34)

with $u(k), v(k), v_z(k)$ having the same definition as in (26). Based on the state space model (27), combining (28) with (29), we have

$$\begin{align*}
\tilde{x}(k+1) &= \tilde{\Phi} \tilde{x}(k) + \tilde{\Gamma} \tilde{u}(k) \\
y_s(k) &= \begin{bmatrix} \bar{H} \tilde{x}(k) + v_s(k), 0 \leq k \leq l \\ \bar{L} \tilde{x}(k-l) + v_s(k), k \geq l \end{bmatrix} \\
\mathbf{w}_s(k) &= \begin{bmatrix} \mathbf{w}_{s_1}(k) \\ \mathbf{w}_{s_2}(k) \end{bmatrix}
\end{align*}$$

(35) \hspace{1cm} (36) \hspace{1cm} (37)

with $v_s(k)$ having the similar definition as in (17). Now we introduce the innovation of $y_s(k)$ as

$$\mathbf{w}_s(k) \triangleq \begin{bmatrix} \mathbf{w}_{s_1}(k) \\ \mathbf{w}_{s_2}(k) \end{bmatrix} = \mathbf{y}_s(k) - \mathbf{\hat{y}}_s(k | k - 1)$$

(37)

where $\mathbf{\hat{y}}_s(k | k - 1)$ is obtained from the Krein space projection of $y_s(k)$ onto the following linear space $L\{y_s(i)\}_{i=0}^{k-1}$. It is obvious that $\mathbf{w}_s(k)$ is a white noise sequence with the covariance matrix $Q_{w_s}(k)$, i.e., $\langle \mathbf{w}_s(k), \mathbf{w}_s(j) \rangle = Q_{w_s}(k) \delta_{kj}$.

It will be seen that the innovation covariance matrix plays an important role in the $H_\infty$ estimation. In fact, it is used to check if the $H_\infty$ estimator $\tilde{z}(k-l | k)$ exists or not. Since $y_s(k)$ contains delay, we shall calculate the covariance matrix $Q_{w_s}(k)$ by applying re-organization innovation analysis.
A. Re-organized Innovation and Riccati Equation

1) Re-organized Innovation Sequence: As is well known, given the measurement sequence \( \{y_s(i)\}_{i=0}^k \), the optimal state estimator \( \hat{x}(k-l \mid k) \) for system (35)-(36) is the projection of \( x(k-l) \) on the linear space spanned by the measurement sequence, denoted by \( \mathcal{L}(y_s(i))_{i=0}^k \) [16]. First, observe from (28) and (36) that for \( 0 \leq k < l \),
\[
\mathcal{L}(y_s(i))_{i=0}^k = \mathcal{L}(y(i))_{i=0}^k
\]
(38)
For \( k \geq l \), it is easy to know that the linear space \( \mathcal{L}(y_s(i))_{i=0}^k \) can be re-organized as
\[
\mathcal{L}(y_s(i))_{i=0}^k = \mathcal{L}\{y_f(i)\}_{i=0}^{k-l}, y(k-l+1), \ldots, y(k)\}
\]
(39)
where
\[
y_f(i) \triangleq \begin{bmatrix}
y(i) \\
\bar{x}(i+l) \\
\end{bmatrix}
\]
(40)
with
\[
v_f(i) = \begin{bmatrix}
v(i) \\
v_z(i+l) \\
\end{bmatrix}, Q_{v_f} = \begin{bmatrix} I_m & 0 \\
0 & -\gamma^2 I_p \end{bmatrix}
\]
(41)
Definition 1: \( \tilde{\zeta}(j | k+i,k), i \geq 0 \) is defined as the projection of \( \zeta(j) \) onto \( \mathcal{L}_f(k+i,k) \), where \( i > 0 \)
\[
\mathcal{L}_f(k+i,k) = \mathcal{L}\{y_f(i)\}_{i=0}^{k-l}, y(k+1), \ldots, y(k+i)\}
\]
(42)
and for \( i = 0 \)
\[
\mathcal{L}_f(k,k) = \mathcal{L}\{y_f(i)\}_{i=0}^{k-l}
\]
(43)
Now, we introduce another innovation associated with the re-organized observations \( y(k+i) \) and \( y_f(k) \) as
\[
w(k+i,k) = y(k+i) - \tilde{y}(k+i \mid k+i-1,k), i > 0
\]
(44)
\[
w(k,k) = y_f(k) - \tilde{y}_f(k \mid k-1,k-1)
\]
(45)
where \( \tilde{y}_f(0 \mid -1,-1) = \begin{bmatrix} \bar{H} \bar{L} \end{bmatrix} \bar{x}(0 \mid -1,-1) = 0 \), and \( \tilde{y}(k+i \mid k+i-1,k) \) is the projection of \( y(k+i) \) on the linear space \( \mathcal{L}_f(k+i-1,k) \) and \( \tilde{y}_f(k \mid k-1,k-1) \) is the projection of \( y_f(k) \) on the linear space \( \mathcal{L}_f(k-1,k-1) \). It is clear that \( w(k,k) \) is the standard Kalman filtering innovation sequence of the observation \( y_f(k) \). Then we have the following relationships:
\[
w(k+i,k) = \bar{H}e(k+i,k) + v(k+i), i > 0
\]
(46)
\[
w(k,k) = \begin{bmatrix} \bar{H} \bar{L} \end{bmatrix} e(k,k) + v_f(k)
\]
(47)
where
\[
e(k+i,k) = \bar{x}(k+i) - \bar{x}(k+i \mid k+i-1,k), i > 0
\]
(48)
\[
e(k,k) = \bar{x}(k) - \bar{x}(k \mid k-1,k-1)
\]
(49)
It is clear that \( e(k+1,k) = e(k+1,k+1) \). The following lemma shows that \( \{w(\cdot,\cdot)\} \) is in fact the innovation sequence.

Lemma 1: \( \{w(0,0), \ldots, w(k_1,k_1), w(k_1+1,k_1), \ldots, w(k_1,k_1)\} \) is the mutually uncorrelated innovation sequence which spans the same linear space as \( \mathcal{L}_f(k,k_1) \) or equivalently \( \mathcal{L}(y_s(0), \ldots, y_s(k)) \).

Proof: The proof is similar to [17].

Remark 1: The re-organized innovation is different from the standard Kalman filtering innovation given by (37), however, they span the same linear space as \( \mathcal{L}(y_s(0), \ldots, y_s(k)) \).

2) Riccati Equation: From (46) and (47), the innovation covariance matrix
\[
Q_w(k+i,k) \triangleq \{w(k+i,k), w(k+i,k)\}, i \geq 0
\]
is given by
\[
Q_w(k+i,k) = \begin{bmatrix} \bar{H}P(k+i,k) \bar{H}^T + Q_v, i > 0 \\
\begin{bmatrix} \bar{H} \\
\bar{L} \end{bmatrix} P(k,k) \begin{bmatrix} \bar{H} \\
\bar{L} \end{bmatrix}^T + Q_{v_f}, i = 0 \end{bmatrix}
\]
(50)
where \( Q_v \) and \( Q_{v_f} \) have similar definition as in (26) and (41) and
\[
P(k+i,k) \triangleq \langle e(k+i,k), e^T(k+i,k) \rangle, i \geq 0
\]
(51)
is the covariance matrix of the one-step ahead state estimation error, which can be computed using the lemma below [17].

Lemma 2: The covariance matrix \( P(j+1,k) \) for \( j = k + 1, k + 2, \ldots \) can be calculated recursively as
\[
P(j+1,k) = \bar{\Phi} P(j,k) \bar{\Phi}^T + \bar{\Gamma} \bar{\Gamma}^T
\]
(52)
where the covariance matrix \( P(k+1,k+1) \) is the solution of the following standard Riccati equation
\[
P(k+1,k+1) = \bar{\Phi} P(k,k) \bar{\Phi}^T + \bar{\Gamma} \bar{\Gamma}^T
\]
(53)
where \( Q_w(j,k) \) is as in (50).

Remark 2: The initial value \( P(0,0) \) in (53) is as \( P(0,0) = \langle \bar{x}(0), \bar{x}(0) \rangle = \begin{bmatrix} \bar{x}_1^2(0) & \bar{x}_2^2(0) & \bar{x}_3^2(0) \end{bmatrix}^T \).

B. Innovation Covariance Matrix \( Q_w(\cdot,\cdot) \)

Definition 2:
\[
P_{k+i,k}^{k+j} \triangleq \langle \bar{x}(k+j), e^T(k+i,k) \rangle, i \geq 0
\]
(54)
is the cross-covariance matrix of the state \( \bar{x}(k+j) \) and the state estimation error \( e(k+i,k) \). And
\[
K_{k+i,k}^{k+j} \triangleq \langle \bar{x}(k+j), w^T(k+i,k) \rangle Q_w^{-1}(k+i,k), i \geq 0
\]
(55)
is the gain matrix of the innovation \( w(k+i,k) \) in the estimation of the state \( \bar{x}(k+j) \), where \( e(k+i,k) \) is as in (48) and \( w(k+i,k) \) is as in (46).
It follows easily from the above definition that
\[ K_{k+i}^{k+i} = R_{k+i}^{k+i} \hat{H}^T Q_w^{-1} (k+i,k) , i > 0 \]  
\[ K_{k+i}^{k+j} = R_{k,j}^{k+j} \left[ \hat{H} \right]^T Q_w^{-1} (k,j), i = 0 \]  
where \( K_{k+i}^{k+i} \) is the Kalman filtering gain matrix. Using the projection formula and taking the above definition into consideration,
\[
\hat{x}(k+j | k+i,k) = \hat{x}(k+j | k+i-1,k) + K_{k+i}^{k+j} w(k+i, k)
\]
and
\[
\hat{x}(k+j | k,k) = \hat{x}(k+j | k-1,k-1) + K_{k+i}^{k+j} w(k,i)
\]
Furthermore, the cross-covariance matrix \( R_{k+i}^{k+j} \) for \( i \geq 0 \) can be computed as [15]:
\[
R_{k+i}^{k+j} = \begin{cases} P(k+j, k) A^T(k+j, k) \cdots A^T(k+j-1, k), i \geq j \\ \Phi^{i-j+2} P(k+i, k), i < j \end{cases}
\]
or be calculated through the recursion form
\[
R_{k+i}^{k+j} = \begin{cases} R_{k+i}^{k+j-1, k} A^T(k+i-1, k), R_{k+i}^{k+j, k} = P(k+j, k), i \geq j \\ \Phi R_{k+i}^{k+j-1} R_{k+i}^{k+i, k} = P(k+i, k), i < j \end{cases}
\]
where \( A(k+i, k), i > 0 \) is given by
\[ A(k+i, k) = \Phi I_n - P(k+i, k) \hat{H}^T Q_w^{-1} (k+i, k) \hat{H}. \]  
For \( i \leq 0 \), we let \( P(k+i, k) = P(k+i, k+i) \) and \( A(k+i, k+i) = A(k+i, k+i) \), where the matrix \( A(k+i, k+i) \) is given by
\[
A(k+i, k+i) = \Phi I_n - P(k+i, k+i) \left[ \begin{array}{c} \hat{H} \\ L \end{array} \right]^T Q_w^{-1} (k+i, k+i) \left[ \begin{array}{c} \hat{H} \\ L \end{array} \right]
\]

**Theorem 1**: The innovation covariance matrix \( Q_w(k) \) is given by
\[
Q_w(k) = \begin{cases} \hat{H} P(k,k-1) \hat{H}^T + Q_w, 0 \leq k < l \\ \hat{H} P(k,k-1) \hat{H}^T \left[ R_{k+i,k-1}^{k+i} \right] L \left[ R_{k+i,k-1}^{k+i} \right]^T L^T \end{cases}
\]
for \( k \geq l \)

where
\[
\mathcal{P}(k) = P(k,k-1) - \sum_{i=0}^{l-1} R_{k+i,k-1}^{k+i} \hat{H}^T Q_w^{-1} (k+i, k-1) \hat{H} \left[ R_{k+i,k-1}^{k+i} \right]^T
\]
and \( Q_w(\cdot) \) and \( P(\cdot, \cdot) \) are as in (50), (52) and (53) , and \( R_{k+i,k-1}^{k+i,k-1,i} = 0, 1, \ldots, l \) are calculated recursively via (60), the covariance matrices \( Q_w, Q_{v_x}, \) and \( Q_{v_y} \) are as given in (26) and (41).

**Proof**: For \( k \geq l \), the innovation is
\[
w_s(k) = \mathbf{y}_s(k) - \hat{\mathbf{y}}_s(k | k-1) = \left[ \begin{array}{c} \hat{H} \\ 0 \end{array} \right] \left[ \begin{array}{c} \bar{x}(k) - \hat{x}(k | k-1) \\ \mathbf{x}(k_1) - \hat{\mathbf{x}}(k | k-1) \end{array} \right] + \mathbf{v}_s(k)
\]
where \( \hat{\mathbf{y}}_s(k | k-1) \) and \( \hat{\mathbf{x}}(k | k-1) \) are the projections of \( \mathbf{y}_s(k) \) and \( \mathbf{x}(k) \) on the linear space of \( \mathcal{L}\{\mathbf{y}_s(i)\}_{i=0}^{k-1} \), respectively. Note that
\[
\hat{\mathbf{x}}(k | k-1) = \hat{\mathbf{x}}(k | k-1, k_l-1)
\]
\[
\hat{\mathbf{x}}(k_1 | k-1) = \hat{\mathbf{x}}(k_1 | k-1, k_l-1)
\]
we have
\[
w_s(k) = \left[ \begin{array}{c} \hat{H} \\ 0 \end{array} \right] \left[ \begin{array}{c} \mathbf{e}(k, k_l-1) \\ \eta(k) \end{array} \right] + \mathbf{v}_s(k)
\]
where
\[
\eta(k) = \mathbf{x}(k_l) - \hat{\mathbf{x}}(k_l | k-1)
\]
\[
\mathbf{e}(k_1, k_l-1) = \mathbf{e}(k_1, k_l-1) - \sum_{i=0}^{l-1} K_{k+i,i}^{k+i} \mathbf{w}(k+i, i, k_l-1)
\]
Then the innovation covariance matrix \( Q_w(k) \) is given by
\[
Q_w(k) = \langle \mathbf{w}_s(k), \mathbf{w}_s(k) \rangle = \left[ \begin{array}{c} \hat{H} \\ 0 \end{array} \right] S(k, k_l-1) \left[ \begin{array}{c} \hat{H} \\ 0 \end{array} \right]^T + Q_{v_s}(k)
\]
where
\[
S(k, k_l-1) = \begin{pmatrix} \langle \mathbf{e}(k, k_l-1), \mathbf{e}(k, k_l-1) \rangle & \langle \mathbf{e}(k, k_l-1), \eta(k) \rangle \\ \langle \eta(k), \mathbf{e}(k, k_l-1) \rangle & \langle \eta(k), \eta(k) \rangle \end{pmatrix}
\]
Observe (51), we have \( \langle \mathbf{e}(k, k_l-1), \mathbf{e}(k, k_l-1) \rangle = P(k, k_l-1) \). Also, by considering the fact that \( \eta(k) \) is uncorrelated with \( \mathbf{w}(k+i, i, k_l-1), i = 0, 1, \ldots, l-1, \) it follows that
\[
\langle \eta(k), \mathbf{e}(k, k_l-1) \rangle = \langle \mathbf{e}(k_1, k_l-1), \mathbf{e}(k_1, k_l-1) \rangle = R_{k_1, k_l-1}
\]
and
\[
Q_{v_s}(k) = \sum_{i=0}^{l-1} \left[ R_{k+i,i}^{k+i,k} \mathcal{P}(k) \right]^T + Q_w(k)
\]
Thus, from (71), the innovation covariance matrix \( Q_w(k) \) for \( k \geq l \) is given by (64). For \( k < l \), since the innovation is given directly as
\[
w_s(k) = \mathbf{y}(k) - \hat{\mathbf{y}}(k | k-1) = \hat{H} \left[ \bar{x}(k) - \hat{x}(k | k-1) \right] + \mathbf{v}(k)
\]
then it’s covariance matrix \( Q_w(k) \) is given by (64).
C. Main Results

Theorem 2: Consider the system (1)-(3) and the associated performance criterion (11). Suppose Assumption 1 is satisfied and the recursion (53) is bounded, we have 1). For a given scalar $\gamma > 0$, an $H_\infty$ estimator $\hat{x}(k+i \mid k)$ that achieves (11) exists if and only if for each $k = l,l+1,\ldots,N, Q_w(k)$ and $Q_v(k)$ have the same inertia, where $Q_w(k)$ is given in Theorem 1 and $Q_v(k)$ is given in (19).

2). The possible central estimator $\hat{x}(k | k)$ is given by

$$\hat{x}(k | k) = L_1 \hat{x}(k | k, k-1) = \tilde{L}_1 \hat{x}(k | k, k-1)$$

where $\hat{x}(k | k, k-1)$ is the projection of $\hat{x}(k)$ on the linear space $L_1(k, k-1), k > l$ and is given as follows

$$\hat{x}(k | k, k-1) = \hat{x}(k | k-1, k-1) + \sum_{i=0}^{l} (P_{k+i,k-1}^i - H^T Q_w^{-1}(k+i, k, k-1)) \times \left[ y(k+i) - H \hat{x}(k+i | k+i-1, k, k-1) \right]$$

with the initial value $\hat{x}(k | k-1, k-1) = \hat{x}(k | k-1, k-2)$ given by the Kalman filter, which is computed recursively as

$$\hat{x}(k | k-1, k-1) = \hat{x}(k | k-1, k-2) + \hat{P}(k-1, k-1) \left[ H L \right] Q_w^{-1}(k-1, k-1) \times \left[ y_f(k-1) - \left[ H L \right] \hat{x}(k-1 | k-2, k-2) \right]$$

with the initial value $\hat{x}(0 | -1, -1) = 0$, $y_f(i)$ is defined in (40), and all covariance matrices as given by (26) and (41).

Proof: It is straightforward to prove 1). And 2) can be obtained similar to [17], [8] for system (27)-(29). ■

Remark 3: By applying re-organization innovation analysis, a new approach to $H_\infty$ fixed-lag smoothing is presented. The obtained results are completely different from our previous work reported in [7] in which a steady-state smoother is investigated by using J-spectral factorization. Moreover, the proposed $H_\infty$ fixed-lag smoother is simpler for calculation compared with the results in [7] as we do not require the state augmentation for the “lag” of the smoothing.

V. CONCLUSION

In this paper, we have investigated the finite horizon $H_\infty$ fixed-lag smoothing for discrete time-varying descriptor systems. An efficient solution, which is new to our knowledge, has been presented. The smoother is given in terms of two RDEs. The approach applied in this paper is the reorganization innovation analysis and the generalized Kalman filtering in Krein space.
