Nonlinear Output Feedback Control for Robust Stability

Chengkang Xie and Mark French

Abstract—In the presence of input and measurement disturbances, an observer and a controller are designed to achieve robust stability for the nominal plant in normal form. By framework of nonlinear gap metric, a robust margin of plant perturbations is obtained, and the controller is shown to be robust to plant perturbations if the gap metric is less than the robust margin.

I. INTRODUCTION

In general, to control a physical plant, a mathematical model (called the nominal plant) for the plant is necessary. But, in practice, the nominal plant cannot completely describe the physical plant, there always exists a plant perturbation. In operation of control, sensors and actuators are setup to measure and input signals, and the sensors and actuators result in measurement errors and input errors, namely, measurement disturbances and input disturbances. A closed-loop could become unstable if a controller cannot tolerate these kinds of uncertainties. EL-Sakkary [1] gave an example that a small uncertainty changed the stability of the closed-loop. So, for control purposes, a basic requirement is that a controller designed for the nominal plant tolerates plant perturbations, measurement disturbances and input disturbances. A closed-loop could become unstable if a controller cannot tolerate these kinds of uncertainties.

Although the study of robustness for control designs is as old as feedback control, even for linear systems effective systematic tools for robust control have only been developed since 1980’s. An appropriate topological structure for studying the robustness of linear systems is the gap metric (graph topology) introduced by Zames and EL-Sakkary [8], [1]. In contrast, other frameworks for studying robustness have restrictions; e.g., the order of parametric uncertainty cannot be changed, a small time delay is not an allowable uncertainty, Un-modeled dynamics or plant perturbations are not allowed, etc.. For nonlinear control, it is difficult to cope with the complexity of nonlinear phenomena even in the absence of disturbances and other uncertainties, the robustness study of nonlinear systems is far less developed than for linear systems. In 1997, Georgiou and Smith [4] established a theory of gap metric for nonlinear case. It provides a powerful tool to study robustness of nonlinear control. Via the framework of nonlinear gap metric, Xie and French [7] successfully designed a robust backstepping controller for state feedback in 2003. Any restrictions on disturbances and plant perturbations have been removed, and the disturbances and perturbations can be un-modeled dynamics. So, it presents that the framework of nonlinear gap metric is a appropriate topological structure for nonlinear feedback control.

In the past two decades, many of control techniques have been developed for nonlinear systems using feedback control. Most of the results, however, assume full state feedback. Efforts to extend some of these results to output feedback have naturally included the idea of designing an observer to estimate the state of a system from its output, see, e.g., [5], [2], [6], [3]. It is a meaningful work to utilize the framework of nonlinear gap metric for the study of output feedback control.

In this paper, we consider a nominal plant in normal form and design an observer and a controller to achieve robust stability of the closed-loop system in the presence of input and measurement disturbances. Then we utilize the results in [4] to obtain the robustness of the closed-loop to plant perturbations which are small in the sense of the gap metric. That is, we show that the controller stabilizes the closed-loop for any perturbed plant in the presence of input and measurement disturbances if the gap metric distance between the nominal and perturbed plant is less than a computable constant. Any restrictions on input and measurement disturbances, and plant perturbations have been removed, and the disturbances and perturbations can be un-modeled dynamics.

II. BACKGROUND AND PROBLEM FORMULATION

In this section we first simply state the background for gap metric robustness. The material here comes from the fundamental paper [4].

A. Background for Gap Metric Robustness

Let $\mathcal{U}$ and $\mathcal{Y}$ be normed signal spaces, and consider a causal nominal plant

$$P : \mathcal{U} \to \mathcal{Y} : u_1 \mapsto y_1$$

and a causal controller

$$C : \mathcal{Y} \to \mathcal{U} : y_2 \mapsto u_2$$

In a control system, there exist measurement disturbance $y_0 \in \mathcal{Y}$ and input disturbance $u_0 \in \mathcal{U}$, which are uncertainties. The standard feedback configuration is shown in Fig. 1,
For simplicity of notation, normally, we write follows.

Thus the closed-loop operator is defined by

\[
\Pi \text{ defined as }
\]

Let \( W \) denote \( U \times Y \), and write

\[
w_0 = \left( \begin{array}{c} u_0 \\ y_0 \end{array} \right), \quad w_1 = \left( \begin{array}{c} u_1 \\ y_1 \end{array} \right), \quad w_2 = \left( \begin{array}{c} u_2 \\ y_2 \end{array} \right)
\]

The closed-loop \([P, C]\) is said to be gain-function (gf-) stable if \( g[\Pi_{M_1/N}] (\alpha) \) remains finite for all \( \alpha \geq 0 \).

It can be seen that if there exists a positive constant \( \Gamma \) such that

\[
\|w_1\| \leq \Gamma \|w_0\|, \quad w_1, w_0 \in W
\]

then \([P, C]\) is stable; if there exists a continuous function \( \gamma(\cdot) > 0 \) such that

\[
\|w_1\| \leq \gamma(\|w_0\|), \quad w_1, w_0 \in W
\]

then \([P, C]\) is gf-stable.

Finally, we define the gap metric between the nominal plant \( P \) and any perturbed plant \( P_1 \) as follows.

\[\delta(P, P_1) = \{0 \}
\]

and the gap metric is defined as

\[
\delta(P, P_1) = \max\{\delta(P, P_1), \delta(P_1, P)\}
\]

where

\[\{0 \}
\]

\[\{0 \}
\]

and \( M_1 \) is the graph of \( P_1 \), namely \( G_{P_1} \).

The significance of the introduction of gap metric lies in the following theorem.

**Theorem 1**: For the feedback system in Fig. 1, let the closed-loop \([P, C]\) be stable. If a plant \( P_1 \) is such that

\[\delta(P, P_1) < \frac{1}{\|\Pi_{M_1/N}\|}
\]

then the closed-loop \([P_1, C]\) is also stable, and

\[\|\Pi_{M_1/N}\| \leq \|\Pi_{M_1/N}\| \frac{1 + \delta(P, P_1)}{1 - \|\Pi_{M_1/N}\|\delta(P, P_1)}
\]

The proof of this theorem can be found in paper [4].

Definition 1, 2, and Theorem 1 provide a complete framework to design a robust controller in the presence of input, measurement disturbances, and plant perturbations. First, for the nominal plant \( P \) design a controller \( C \) such that the closed-loop operator \( H_{P,C} \) is stable, namely, the operator \( \Pi_{M_1/N} \) has a finite induced norm, or the signals satisfy (1). Second, by Theorem 1, we get a plant robust margin \( \|\Pi_{M_1/N}\|^{-1} \), the controller \( C \) thus can stabilize any closed-loop \([P_1, C]\) if the directed gap metric \( \delta(P, P_1) \) is properly small. The idea to design a robust gf-stable controller is similar.
B. Problem Formulation

Consider following nominal plant in normal form

\[ \mathcal{P}(x_1^0) : \dot{x}_{11} = x_{12} \]
\[ \vdots \]
\[ \dot{x}_{1(n-1)} = x_{1n} \]
\[ \dot{x}_1n = \varphi(x_{11}, \ldots, x_{1n}) + u_1 \]
\[ y_1 = x_{11} \]

where
\[ x_1^0 = (x_{11}^0, \ldots, x_{1n}^0)^T \]
is the initial condition. Well-posedness of the differential equations guarantees that of the feedback configuration, hence, for the well-posedness of the differential equations, we assume that \( \varphi(0) = 0 \), and \( \varphi \) is Lipschitz continuous, that is, there exist a constant \( L \) such that for any \( \omega_1, \omega_2 \in \mathbb{R}^n \), it hold

\[ |\varphi(\omega_1) - \varphi(\omega_2)| \leq L \|\omega_1 - \omega_2\| \]

where we utilize \( \|\cdot\| \) to denote the Euclidean norm.

We introduce following notations

\[ x_1 = \begin{pmatrix} x_{11} \\ x_{12} \\ \vdots \\ x_{1n} \end{pmatrix}, \quad A = \begin{pmatrix} 0 & 1 & 0 & \cdots & 0 & 0 \\ 0 & 0 & 1 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 0 & 1 \\ 0 & 0 & 0 & \cdots & 0 & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 0 \\ \vdots \\ 0 \\ 0 \end{pmatrix} \]

\[ C = (1, 0, \ldots, 0) \]

then the plant can be rewrite as

\[ \mathcal{P}(x_1^0) : \dot{x}_1 = Ax_1 + B(\varphi(x_1) + u_1), \quad x_1(0) = x_1^0 \]
\[ y_1 =Cx_1 \]

(4a)
(4b)

Take signal spaces

\[ \mathcal{U} = L^\infty(\mathbb{R}), \quad \mathcal{Y} = L^\infty(\mathbb{R}) \]

then

\[ \mathcal{P}(x_1^0) : L^\infty(\mathbb{R}) \rightarrow L^\infty(\mathbb{R}) : u_1 \mapsto y_1 \]

The norm for the space \( L^\infty(\mathbb{R}) \) is defined as the normal norm \( \|\cdot\|_\infty \).

The problem is to design a controller such that the closed-loop system is stable or \( \gamma \)-stable. Alternatively, such that there exist a constant \( \Gamma \) and a gain function \( \gamma(\cdot) \) which satisfy (1) and (2).

III. Design of Controller

Firstly, we chose a vector

\[ K = (k_1, \ldots, k_n) \]

such that \( A_0 = A + BK \) is Hurwitz. Secondly, we chose positive constants \( \alpha_i, i = 1, \ldots, n \) such that the roots of the equation

\[ s^n + \alpha_1 s^{n-1} + \cdots + \alpha_{n-1} s + \alpha_n = 0 \]

are in the left-half plane, and let

\[ D = (\alpha_1, \alpha_2, \ldots, \alpha_n)^T \]

Then we design an observer as

\[ \dot{x}_2 = A\hat{x}_2 - D(y_2 - \hat{y}_2) + BK\hat{x}_2, \quad \hat{x}_2(0) = x_1^0 \]

(5a)

\[ \dot{\hat{y}}_2 = C\hat{x}_2 \]

(5b)

Lastly, we define a controller as

\[ C(\hat{x}_2^0) : \]

\[ u_2 = \varphi(-y_2) + K\hat{x}_2 \]

(6a)

\[ \dot{x}_2 = A\hat{x}_2 + D(y_2 - \hat{y}_2) + BK\hat{x}_2, \quad \hat{x}_2(0) = x_1^0 \]

(6b)

\[ \dot{\hat{y}}_2 = C\hat{x}_2 \]

(6c)

IV. Robustness Analysis

First we prove a lemma about the estimate of the observer error.

Lemma 1: Let \( x_1 \) be the state of the plant in (4), and \( \hat{x}_2 \) be observer state in (5), and let

\[ \hat{x} = x_1 + \hat{x}_2 \]

be the perturbed observer error. Then there exist positive constants \( \beta \) such that

\[ \| \hat{x} \|_{\infty} \leq b\|\hat{x}_1^0\| + \beta\|u_0, y_0\|_{\infty} \]

(7)

where

\[ \hat{x}_1^0 = x_1^0 + \hat{x}_2^0 \]

Proof: Note that

\[ u_1 = u_0 - u_2, \quad y_2 = y_0 - y_1 \]

then the closed-loop \([\mathcal{P}(x_1^0), C(\hat{x}_2^0)]\) can be written as

\[ \dot{x}_1 = Ax_1 + B(\varphi(y_1) - \varphi(-y_2) - K\hat{x}_2 + u_0), \quad x_1(0) = x_1^0 \]

\[ \dot{x}_2 = A\hat{x}_2 + D(y_0 - C(x_1 + \hat{x}_2)) + BK\hat{x}_2, \quad \hat{x}_2(0) = \hat{x}_2^0 \]

From above two equations, we obtain

\[ \dot{x} = A_1\hat{x} + Dy_0 + B(\varphi(y_1) - \varphi(-y_2) + u_0), \quad \hat{x}(0) = \hat{x}_1^0 \]

(8)

where

\[ A_1 = A - DC \]

and it can be verified that the matrix \( A_1 \) is Hurwitz.
Solving (8), we obtain
\[ \dot{x} = e^{A_1 t}x^{0} + \int_{0}^{t} e^{A_1 (t-\tau)} \times \]
\[ (Dy_0(\tau) + B(\varphi(y_1(\tau)) - \varphi(-y_2(\tau)) + u_0(\tau))) \, d\tau \]
\[ (9) \]
Since \( A_1 \) is Hurwitz, all the real parts of the eigenvalues of \( A_1 \) are negative. We take a positive constant \( \mu \) such that \(-\mu\) is greater than all the real parts of the eigenvalues of \( A_1 \), then there exists a positive constant \( b \) such that
\[ \|e^{A_1 t}\| \leq be^{-\mu t} \]
On the other hand, by Lipschitz condition, it holds that
\[ |\varphi(y_1) - \varphi(-y_2)| \leq L|y_1 + y_2| = L|y_0| \]
Therefore, from (9), we obtain
\[ \|\dot{x}(t)\| \]
\[ \leq \|x^{0}\| \cdot \|e^{A_1 t}\| + \int_{0}^{t} d\tau \|e^{A_1 (t-\tau)}\| \times \]
\[ \left( \|Dy_0(\tau)\| + \|\varphi(y_1(\tau)) - \varphi(-y_2(\tau))\| + \|u_0(\tau)\| \right) \]
\[ \leq \|x^{0}\|e^{-\mu t} \]
\[ + \int_{0}^{t} be^{-\mu (t-\tau)} (\|D\| + L)\|y_0\|_{\infty} + \|u_0\|_{\infty}) d\tau \]
\[ \leq b\|x^{0}\| + \frac{b}{\mu} (\|D\| + L)\|y_0\|_{\infty} + \|u_0\|_{\infty}) \]
\[ \leq b\|x^{0}\| + \beta\|(u_0, y_0)\|_{\infty} \]
Write
\[ \beta = \frac{b\sqrt{2}}{\mu} \max\{\|D\| + L, 1\} \]
then we obtain (7), and complete the proof.

Now we state and prove the main result.

**Theorem 2:** Let the plant \( P(x_1^0) \) and controller \( C(x_2^0) \) be defined by (3) and (6). Then

1. There exists a continuous function \( \gamma : \mathbb{R}_+^3 \to [0, +\infty) \) such that for all \( (u_0, y_0)^T \in L^\infty(\mathbb{R}^+) \times L^\infty(\mathbb{R}^+) \), it holds
\[ \|(u_1, y_1)^T\|_\infty \leq \gamma \left( \|(u_0, y_0)^T\|_\infty, \|\tilde{x}_0\|, \|x_0^0\|_\infty \right) \]
(10)
that is, the closed-loop \([P(x_1^0), C(x_2^0)]\) is g.f-stable.

2. If \( x_1^0 \) is zero, by setting \( \tilde{x}_0 \) to be zero, there exists a positive constant \( \Gamma \) such that for all \( (u_0, y_0)^T \in L^\infty(\mathbb{R}^+) \times L^\infty(\mathbb{R}^+) \), it holds
\[ \|(u_1, y_1)^T\|_\infty \leq \Gamma \|(u_0, y_0)^T\|_\infty \]
(11)
that is, the closed-loop \([P(0), C(0)]\) is stable.

**Proof:** Let \( Q \) be the solution of the equation
\[ (A + BK)^TQ + Q(A + BK) = -2I \]
and consider the Lyapunov function
\[ V(t) = V(x_1(t)) = x_1^TQx_1 \]
then along the trajectories of the closed-loop, we have
\[ \dot{V} = \dot{x}_1^TQx_1 + x_1^TQ \dot{x}_1 \]
\[ \dot{V} = (Ax_1 + B(\varphi(y_1) + u_1))^TQx_1 \]
\[ \begin{align*}
&= Ax_1^TQ(Ax_1 + B(\varphi(y_1) + u_1)) \\
&\quad + x_1^TQ(Ax_1 + B(\varphi(y_1) + u_0 - u_2)) \\
&\quad + x_1^TQ(Ax_1 + B(\varphi(y_1) + u_0 - u_2)) \\
&\quad + x_1^TQ(Ax_1 + B(\varphi(y_1) + u_0 - u_2)) \]
\[ \begin{align*}
&= \left( Ax_1 + B(\varphi(y_1) + u_0 - y_2) - K\tilde{x}_2 \right)^T Qx_1 \\
&\quad + x_1^TQ(Ax_1 + B(\varphi(y_1) + u_0 - y_2) - K\tilde{x}_2) \\
&\quad = -2x_1^T + 2B^TQ(x_1(\varphi(y_1) - \varphi(-y_2) - K\tilde{x} + u_0) \\
&\quad = -2\|x_1\|^2 + 2B^TQx_1(\varphi(y_1) - \varphi(-y_2) - K\tilde{x} + u_0) \\
&\quad \leq -2\|x_1\|^2 + 2B^TQx_1(\varphi(y_1) - \varphi(-y_2) - K\tilde{x} + u_0) \\
\end{align*} \]
Let
\[ Q = \{q_{ij}\}_{n \times n} \]
and
\[ q_1 = \max_{1 \leq j \leq n} \{|q_{1j}|\} \]
then
\[ B^TQx_1 \leq q_1\|x_1\| \]
On the other hand, from the Lipschitz condition and Lemma 1, we obtain
\[ \varphi(y_1) - \varphi(-y_2) - K\tilde{x} + u_0 \leq L\|y_0\|_{\infty} + \|K\|\|\tilde{x}\|_{\infty} + \|u_0\|_{\infty} \]
\[ \leq l\sqrt{2}(\|(u_0, y_0)^T\|_{\infty} + \|K\|\|\tilde{x}_0\| + \beta\|(u_0, y_0)^T\|_{\infty}) \]
\[ \leq b^*\|\tilde{x}_0\| + \beta^*\|(u_0, y_0)^T\|_{\infty} \]
where
\[ l = \max\{L, 1\} \]
\[ b^* = \|K\| \]
\[ \beta^* = l\sqrt{2} + \|K\|\beta \]
Hence
\[ 2B^TQx_1(\varphi(y_1) - \varphi(-y_2) - K\tilde{x} + u_0) \]
\[ \leq 2q_1\left( b^*\|\tilde{x}_0\| + \beta^*\|(u_0, y_0)^T\|_{\infty} \right)\|x_1\| \]
Therefore
\[ \dot{V} = -2\|x_1\|^2 + 2B^TQx_1(\varphi(y_1) - \varphi(-y_2) - K\tilde{x} + u_0) \]
\[ \leq -\|x_1\|^2 - \|\tilde{x}\|^2 \]
\[ + 2q_1\left( b^*\|\tilde{x}_0\| + \beta^*\|(u_0, y_0)^T\|_{\infty} \right)\|x_1\| \]
By Young’s Inequality, we obtain that
\[ \dot{V} \leq -\|x_1\|^2 + q_1^2 (b^* \|\ddot{x}_0\| + \beta^* \|(u_0, y_0)T\|_\infty)^2 \]
then \( V \) decreases monotonically outside the compact set
\[ R = \{ x_1 \in \mathbb{R}^n | |x_1| \leq q_1 (b^* \|\ddot{x}_0\| + \beta^* \|(u_0, y_0)T\|_\infty) \} \]
So, if
\[ x^0_1 \leq b^* \|\ddot{x}_0\| + \beta^* \|(u_0, y_0)T\|_\infty \]
then \( V(t) \) remains in \( R \); if
\[ x^0_1 > b^* \|\ddot{x}_0\| + \beta^* \|(u_0, y_0)T\|_\infty \]
then \( V(t) \) monotonically decreases from \( t = 0 \) until \( x_1 \) reaches \( R \). Therefore
\[ V(t) \leq \max \{ V(x^0_1), \nabla \} \]
where
\[ \nabla = \sup \left\{ V(x_1) | |x_1| \leq q_1 (b^* \|\ddot{x}_0\| + \beta^* \|(u_0, y_0)T\|_\infty) \right\} \]
Note that
\[ \lambda(Q) \leq \Lambda(Q) \leq \lambda(Q) \]
where \( \lambda(Q) \) and \( \lambda(Q) \) are the maximum and minim eigenvalues of matrix \( Q \) respectively, then
\[ \sup \left\{ V(x_1) | |x_1| \leq q_1 (b^* \|\ddot{x}_0\| + \beta^* \|(u_0, y_0)T\|_\infty) \right\} \]
\[ = \sup \times \left\{ \lambda(Q) | |x_1| \leq q_1 (b^* \|\ddot{x}_0\| + \beta^* \|(u_0, y_0)T\|_\infty) \right\} \]
\[ = \lambda(Q) \left( b^* \|\ddot{x}_0\| + \beta^* \|(u_0, y_0)T\|_\infty \right)^2 \]
therefore
\[ \|x_1\| \leq \sqrt{\frac{V}{\lambda(Q)}} \leq \max \left\{ \sqrt{\frac{\lambda(Q)}{\lambda(Q)}}, X \right\} \]
where
\[ X = q_1 \sqrt{\lambda(Q)} (b^* \|\ddot{x}_0\| + \beta^* \|(u_0, y_0)T\|_\infty) \]
Write
\[ g(p, q, r) = \max \left\{ \sqrt{\lambda(Q)}, q_1 \sqrt{\lambda(Q)} (b^* q + \beta^* p) \right\} \]
then the above inequality can be rewritten as
\[ \|x_1\| \leq g \left( \|(u_0, y_0)T\|_\infty, \|\ddot{x}_0\|, \|x_0\| \right) \]
So
\[ \|y_1\|_\infty \leq g \left( \|(u_0, y_0)T\|_\infty, \|\ddot{x}_0\|, \|x_0\| \right) \]
since the left hand side of the inequality is a constant.
Therefore we obtain our estimate for \( \|y_1\|_\infty \) as follows.
\[ \|y_1\|_\infty = \|x_1\|_\infty \leq \|x_1\|_\infty \leq g \left( \|(u_0, y_0)T\|_\infty, \|\ddot{x}_0\|, \|x_0\| \right) \]
Next we estimate \( \|u_1\|_\infty \). First
\[ u_1 = u_0 - u_2 \]
\[ = u_0 - \phi(y_2) - K \ddot{x}_2 \]
\[ = u_0 + \phi(y_1) - \phi(y_2) - K(x_1 + \ddot{x}_2) - \phi(y_1) + K x_1 \]
\[ = u_0 + \phi(y_1) - \phi(y_2) - K \ddot{x} - \phi(y_1) + K x_1 \]
Note that \( \phi \) is Lipschitz, and \( \phi(0) = 0 \), hence
\[ \|u_1\|_\infty \leq \|u_0\|_\infty + \|\phi(y_1) - \phi(y_2)\|_\infty + ||K|| \|\ddot{x}_2\|_\infty \]
\[ + ||\phi(y_1) - \phi(y_1)\|_\infty + ||K|| \|x_1\|_\infty \]
\[ \leq \|u_0\|_\infty + L \|y_1 + y_2\|_\infty + ||K|| \|\ddot{x}_2\|_\infty \]
\[ + L \|y_1\|_\infty + \|K\| \|x_1\|_\infty \]
\[ \leq \|u_0\|_\infty + L \|y_2\|_\infty \]
\[ + ||K|| \left( b \|\ddot{x}_0\| + \beta \|(u_0, y_0)T\|_\infty \right) \]
\[ + L \|y_1\|_\infty + \|K\| \|x_1\|_\infty \]
\[ \leq \sqrt{2} \|u_0\|_\infty + L \|y_2\|_\infty \]
\[ + \|K\| \left( b \|\ddot{x}_0\| + \beta \|(u_0, y_0)T\|_\infty \right) \]
\[ + (L + ||K||) g \left( \|(u_0, y_0)T\|_\infty, ||\ddot{x}_0||, ||x_0|| \right) \]
Write
\[ h(p, q, r) = \sqrt{2} p + ||K|| (b q + \beta p) + (L + ||K||) g (p, q, r) \]
then we obtain
\[ \|u_1\|_\infty \leq h \left( \|(u_0, y_0)T\|_\infty, ||\ddot{x}_0||, ||x_0|| \right) \]
Therefore, write
\[ \gamma(p, q, r) = \left( g(p, q, r)^2 + h(p, q, r)^2 \right)^{\frac{1}{2}} \]
then we have built up the following inequality
\[ \|(u_1, y_1)T\|_\infty \leq \left( \|u_1\|_\infty^2 + \|u_1\|_\infty^2 \right)^{\frac{1}{2}} \]
\[ \leq \left[ g \left( \|(u_0, y_0)T\|_\infty, ||\ddot{x}_0||, ||x_0|| \right)^2 \right. \]
\[ + \left. h \left( \|(u_0, y_0)T\|_\infty, ||\ddot{x}_0||, ||x_0|| \right)^2 \right]^{\frac{1}{2}} \]
\[ = \gamma \left( \|(u_0, y_0)T\|_\infty, ||\ddot{x}_0||, ||x_0|| \right) \]
that is, the closed-loop is gf-stable.
\[
\gamma(p, 0, 0) = (g(p, 0, 0)^2 + h(p, 0, 0)^2)^{\frac{1}{2}}
\]
\[
= \left( q_1 \beta^* \sqrt{\lambda(Q)p} \right)^2
\]
\[
+ \left( \sqrt{\frac{L}{2} + \|k\|\beta + (L + \|k\|)q_1 \beta^* \sqrt{\lambda(Q)p}} \right)^2 \frac{1}{2}
\]
\[
= \left( q_1^2 \beta^* \sqrt{\lambda(Q)} \right)^2
\]
\[
+ \left( \sqrt{\frac{L}{2} + \|k\|\beta + (L + \|k\|)q_1 \beta^* \sqrt{\lambda(Q)}} \right)^2 \frac{1}{2}
\]

Let
\[
\Gamma = \left( (q_1^2 \beta^* \sqrt{\lambda(Q)} \right)^2
\]
\[
+ \left( \sqrt{\frac{L}{2} + \|k\|\beta + (L + \|k\|)q_1 \beta^* \sqrt{\lambda(Q)}} \right)^2 \frac{1}{2}
\]

then, it follows that (11) holds.

A robustness to plant perturbations can be given as follows.

**Theorem 3:** Let the plant \( P(x_0^0) \) and controller \( C(x_0^1) \) be defined by (3) and (6). Then there exists \( \Gamma > 0 \) such that if a plant \( P_1 \) satisfies
\[
\delta(P(0), P_1) < \frac{1}{\Gamma}
\]
\[
\text{then the closed-loop } [P_1, C(0)] \text{ is also stable, and}
\]
\[
\|\Pi_{M_1/\mathcal{N}}\| \leq \Gamma \left( 1 + \delta(P(0), P_1) \right) \frac{1}{1 - \delta(P(0), P_1)}
\]

**Proof:** By Theorem 2, we have shown that there exists \( \Gamma > 0 \) such that
\[
\|\Pi_{M/\mathcal{N}}\| \leq \Gamma
\]

Then, if
\[
\delta(P, P_1) < \frac{1}{\Gamma}
\]

it holds that
\[
\delta(P, P_1) < \frac{1}{\|\Pi_{M_1/\mathcal{N}}\|}
\]

Hence, by Theorem 1, the closed-loop \([P_1, C(0)]\) is stable, and (14) holds, and the proof is completed.

V. Conclusions and Comments

Within the framework of nonlinear gap metric, an output feedback control design procedure for robust stability has been established in the presence of input, measurement disturbances, and plant perturbations. Any restriction on input and measurement disturbances is not required. Unmodeled plant perturbations such as time delay are allowable uncertainties. So, the work in this paper shows that the framework of nonlinear gap metric is an appropriate topological structure for robust output feedback control designs. This paper therefore represents a start to apply the framework of nonlinear gap metric to output feedback control designs for robust stability.

A global Lipschitz condition is imposed on the nonlinearity of the nominal plant, which is for a global result of input and measurement disturbances; a relaxation of the requirement to local Lipschitz condition leads a semi-global results.
