Abstract: This paper investigates the controller synthesis problem of uncertain systems with time varying delays. A robust controller with delay compensation is proposed, based on Lyapunov function method. The stability criterion of the closed-loop system, which is dependent on the size of the time delay and the size of its derivative, is derived in the form of linear matrix inequalities (LMI). Examples show that the results using the method in this paper are less conservative than most existing results by other methods. Copyright © 2002 IFAC

Keywords: delay, Lyapunov methods, stability, stabilization, uncertainty.

1. INTRODUCTION

The study of stability and stabilization of time delay systems has attracted considerable attention over the past several decades because of their practical applications (Boyd.S., et al., 1994)-(Zheng Feng., et al., 1995). In these works, the derived results can be classified into two categories: delay independent results (Boyd.S., et al., 1994)(M.S.Mahmoud., et al., 1999)(M.S.Mahmoud., et al., 2001(Kim J.H., et al., 1996)(Choi H.H., et al., 1996) and delay dependent results (Cao Y.Y., et al., 1998)(Cao Y.Y., et al., 2000)(Carlos E. De Souze., et al., 1999)(M.S.Mahmoud, et al., 2001)(Li Xi, et al., 1997). Generally, the delay dependent results are less conservative than the delay independent ones when the time delay is small.

Recently, a number of research works focused on the study of delay dependent methods via memoryless controller for uncertain systems with time delay. When time delay is time varying or constant, some memoryless controller design methods (Cao Y.Y., et al., 1998)(Cao Y.Y., et al., 2000)(Carlos E. De Souze., et al., 1999)(M.S.Mahmoud, et al., 2001)(Li Xi, et al., 1997) were proposed, based on the Lyapunov function method and first order transformation (Gu Keqin., et al., 2001). To reduce the conservatism of the existing results, Gu (2000) used the discretized Lyapunov functional approach to propose a new design method of a robust controller. The given controller can stabilize the original system with larger maximum allowed value of time delay than the existing ones by other methods. However, only systems with polytopic uncertainty and constant delay were addressed in (Gu Keqin., et al., 2000). It is difficult to extend the method in (Gu Keqin., et al., 2000) to systems with norm-bounded uncertainties and time varying delays. To study stabilization of time delay systems, a memoryless controller and a memory controller were proposed. See (Cao Y.Y., et al., 1998)(Cao Y.Y., et al., 2000)(Carlos E. De Souze., et al., 1999)(M.S.Mahmoud, et al., 1999)(M.S.Mahmoud, et al., 2001)(Li Xi, et al., 1997)(Gu Keqin., et al., 2000)(Gu Keqin., et al., 2001)(Kim J.H., et al., 1996)(Sophie Tarbouriech, et al., 1999)(Choi H.H., et al., 1996) for the memoryless case and (Young Soo Moon, et al., 2001)(Zheng Feng, et al., 1995) for the memory case. Although the proposed memoryless controllers are easy to implement, they often tend to be more conservative, especially when the past information on the system can be employed. By using past state or past input information, delay dependent controllers were designed in (Young Soo Moon, et al., 2001)(Zheng Feng, et al., 1995) and were shown by examples to be less conservative than memoryless controllers. The shortcoming of the methods (Young Soo Moon, et al., 2001)(Zheng Feng, et al., 1995) is that the time delay must be assumed to be known and constant.

In this paper, we investigate the problem of delay dependent robust controller design for systems with norm-bounded uncertainties and time varying delays. To obtain a transformed system, a neutral model transformation and first-order transformation (M.S.Mahmoud, et al., 2001) are employed simultaneously. Unlike the memoryless controllers (Cao Y.Y., et al., 1998)(Cao Y.Y., et al., 2000)(Carlos E. De Souze., et al., 1999)(M.S.Mahmoud, et al., 2001)(Li Xi, et al., 1997)(Gu Keqin, et al., 2000), the given controller provides feedback of the current state and past state information. The advantages of our method are two. First, more information on the state is used to implement the controller. Seconds, the time delay can be time varying and the exact value of the time delay is not required to be known. The derived stability criterions are expressed in terms of LMI, which can be effectively solved by using various optimization algorithms (Boyd.S., et al., 1994).

Notation: $R^n$ denotes the n-dimensional Euclidean space, $R^{m×n}$ is the set of $n×m$ real matrices, $I$ is the identity matrix, $||\cdot||$ stands for the induced matrix 2-norm. The notation $X > 0$ (respectively, $X \geq 0$), for $X \in R^{m×n}$ means that the matrix $X$ is a real symmetric positive definite (respectively, positive semi-definite). $C_0$ denotes the set of all continuous functions, from $[-\infty, 0]$ to $R^n$.

2. SYSTEM DESCRIPTION AND MAIN RESULTS

Consider the following uncertain system with time varying delay
\[
\dot{x}(t) = [A + \Delta A(t)]x(t) + [A_1 + \Delta A_1(t)](x(t - \tau(t))) + [B + \Delta B(t)]u(t) ,
\]
where \( x(t) \in \mathbb{R}^n \) and \( u(t) \in \mathbb{R}^m \) are the system state and the control input, respectively. \( \tau(t) \) represents the time delay which is continuously differentiable and satisfies \( 0 \leq \tau(t) \leq \bar{\tau} \) and \( \tau(t) \leq d < 1 \). \( \Phi(t) \in C_0 \) is the initial function. \( A, A_1 \) and \( B \) are constant matrices of appropriate dimensions. \( \Delta A(t) \), \( \Delta A_1(t) \) and \( \Delta B(t) \) denote the parameter uncertainties which satisfy
\[
[\Delta A(t) \quad \Delta A_1(t) \quad \Delta B(t)] = D F(t) [E_1 \quad E_2 \quad E_3]
\]
where \( D, E_1, E_2 \) and \( E_3 \) are known matrices and \( F(t) \) is unknown time varying matrix which satisfies \( \| F(t) \| \leq 1 \). The following Lemmas will be used in our main result.

**Lemma 1 (Carlos E. De Souza, et al., 1999):** For any \( x, y \in \mathbb{R}^{n_{max}} \) and for any positive symmetric definite matrix \( P \in \mathbb{R}^{n_{max}} \),
\[
2x^T y \leq x^T P^{-1} x + y^T P y .
\]
(2). Let \( A, D, E \) and \( F \) represent real matrices of appropriate dimensions with \( \| F \| \leq 1 \). Then we have:
(a) For any scalar \( \varepsilon > 0 \),
\[
DF E + E^T P D^T \leq \varepsilon^{-1} D D^T + \varepsilon E^T E .
\]
(b) For any matrix \( P = P^T > 0 \) and scalar \( \varepsilon > 0 \) such that \( \varepsilon I - E E^T \leq 0 \),
\[
(A + D F E) P (A + D F E)^T \leq A P A^T + A P E^T (\varepsilon I - E E^T)^{-1} E P A^T + \varepsilon D D^T .
\]
(c) For any matrix \( P = P^T > 0 \) and scalar \( \varepsilon > 0 \) such that \( P - \varepsilon D D^T > 0 \),
\[
(A + D F E)^T P^{-1} (A + D F E) \leq (A + D F E)^T (P - \varepsilon D D^T)^{-1} A + \varepsilon^{-1} E E^T .
\]

**Lemma 2 (Dong Yue and Sangchul won, 2001):** Consider an operator \( D(\cdot) : \mathbb{R}^n \rightarrow \mathbb{R}^n \) with
\[
D(\hat{y}(t)) = y(t) + \hat{B} \int_{t-k}^{t} y(s) ds ,
\]
where \( y(t) \in \mathbb{R}^n \) and \( \hat{B} \in \mathbb{R}^{n_{max}} \). For a given scalar \( \delta \), where \( 0 < \delta < 1 \), if there exists a positive definite symmetric matrix \( P \) such that
\[
[ -\delta P \quad \hat{B} P \quad \delta P ] \leq 0 , \quad [ -P \quad \hat{B} P \quad -P ] \leq 0 ,
\]
then the operator \( D(\hat{y}(t)) \) is stable.

Next, we give our main result.

**Theorem 1:** Suppose that scalars \( \bar{\tau} > 0 \) and \( d < 1 \) are given. Then the system (1) with the control
\[
\begin{equation}
\begin{aligned}
\dot{x}(t) &= [A + \Delta A(t)]x(t) + [A_1 + \Delta A_1(t)](x(t - \tau(t))) + [B + \Delta B(t)]u(t), \\
\end{aligned}
\end{equation}
\]
\[
is asymptotically stable for any \( \tau(t) \) satisfying \( 0 \leq \tau(t) \leq \bar{\tau} \) and \( \tau(t) \leq d < 1 \), if there exist positive definite matrices \( X, X_k \) \((k = 1, 2, 3) \), \( Y_i \) \((i = 1, 2, 3, 4) \) and matrix \( Y \in \mathbb{R}^{m_{max}} \) and positive scalars \( \varepsilon_j \) \((j = 1, 2, \ldots, 7) \) such that
\[
\begin{equation}
\begin{aligned}
\begin{bmatrix}
\Sigma & -\frac{1}{2} (A + A_1) A_k' \Omega_k \\
-\frac{1}{2} A_k (A + A_1)'^T & -\frac{1}{2} Y_1 \\
\Omega_1 & \Omega_2
\end{bmatrix} &< 0 \\
\end{aligned}
\end{equation}
\]
where
\[
\begin{equation}
\begin{aligned}
\begin{bmatrix}
-Y_2 \quad Y_2 A_k'^T \\
A_k Y_2 - X_1 + \varepsilon_1 D D^T & 0 \\
E_2 Y_2 & 0 - \varepsilon_2 I
\end{bmatrix} &< 0 \\
\begin{bmatrix}
-\varepsilon_1 Y_k A_k'^T \\
A_k Y_k - X_2 + \varepsilon_1 D D^T & 0 \\
E_2 Y_k & 0 - \varepsilon_2 I
\end{bmatrix} &< 0 ,
\end{aligned}
\end{equation}
\]
\[
\begin{equation}
\begin{aligned}
\begin{bmatrix}
-\varepsilon_1 Y_k A_k'^T & -Y_4 \quad Y_4 B^T \\
Y_k Y^T & -Y_k Y^T E_k^T & Y E_k^T \\
E_2 Y_k & 0 & - \varepsilon_2 I
\end{bmatrix} &< 0 ,
\end{aligned}
\end{equation}
\]
and
\[
\begin{equation}
\begin{aligned}
\Sigma &= X (A + A_1)'^T + (A + A_1) X + BY + Y^T B^T + \\
&+ \varepsilon_1 (A + A_1) + \varepsilon_2 (A + A_1) D D^T + \\
&+ \varepsilon_3 A_k (X_1 + X_2 + X_3) A_k' + \varepsilon_4 Y_i \\
\Omega_k &= \begin{bmatrix}
XE_k & \frac{1}{2} X Y E_k & \frac{1}{2} Y X & 0 & X E_k^T & Y^T E_k^T
\end{bmatrix} \\
\Omega_k' &= \begin{bmatrix}
-\varepsilon_1 Y_k A_k'^T & -\varepsilon_1 Y_k A_k'^T \\
-\varepsilon_1 Y_k A_k'^T & -\varepsilon_1 Y_k A_k'^T \\
-\varepsilon_1 Y_k A_k'^T & -\varepsilon_1 Y_k A_k'^T \\
-\varepsilon_1 Y_k A_k'^T & -\varepsilon_1 Y_k A_k'^T \\
-\varepsilon_1 Y_k A_k'^T & -\varepsilon_1 Y_k A_k'^T \\
-\varepsilon_1 Y_k A_k'^T & -\varepsilon_1 Y_k A_k'^T
\end{bmatrix} \\
\varepsilon &= \text{diag} \left( \varepsilon_1, \varepsilon_1, \varepsilon_1, \varepsilon_1, \varepsilon_1, \varepsilon_1 \right) .
\end{aligned}
\end{equation}
\]
\]

**Proof:** Define a neutral transformation as
\[
\begin{equation}
\begin{aligned}
z(t) = x(t) + \int_{t-\bar{\tau}}^{t} A_k x(s) ds .
\end{aligned}
\end{equation}
\]
Using (8), we design a controller as
\[
\begin{equation}
\begin{aligned}
u(t) = K z(t) ,
\end{aligned}
\end{equation}
\]
where \( K \) is a constant matrix that will be designed later.

Taking the time derivative of \( z(t) \) and combining (1), (9) and Leibniz-Newton formula, we obtain the following transformed system
\[
\dot{z}(t) = (A + A_1)x(t) + \Delta A(t)x(t) + \Delta A_1(t)x(t) - \nabla f(x(t))
\]
for \(t > T/2\)

\[-A_1 \int_{t-T/2}^{t} (\Delta A(s))x(s) + (A_1 + \Delta A_1(s))x(s) - \nabla f(x(s))ds \]

\[+(B + \Delta B(s))K(s)\]

where \(K(s)\) is symmetric positive definite. Moreover, \(V_1(x_i)\) and \(V_2(x_i)\) are continuously twice differentiable in \(x\) and once in \(t\).

Next, to prove the negative of time derivative of \(V(x_i)\), we will consider two cases.

First, we consider the case when \(\tau(t) < \frac{T}{2}\).

We rewrite (10) as

\[
\begin{align*}
\dot{V}(t) &= \dot{V}_1(x_i) + \dot{V}_2(x_i) \\
V_1(x_i) &= \int_{t-T/2}^{t} x^T(s)Qx(s)ds + \int_{t-T/2}^{t} \int x^T(v)Qx(v)dvds \\
V_2(x_i) &= \int_{t-T/2}^{t} \int x^T(v)Gx(v)dvds + \int_{t-T/2}^{t} \int x^T(s)Gx(s)ds \]
\end{align*}
\]

where \(\oplus\) is "+" as \(\tau(t) < \frac{T}{2}\) and "-" as \(\tau(t) \geq \frac{T}{2}\).

Taking the time derivative of \(V_i(x_i)\) with respect to time \(t\) and combining (8), we obtain

\[
\dot{V}_1(x_i) = 2\zeta^T(t)[P(A + A_1) + PBK]z(t)
\]

Using Lemma 1 and noting that \(\frac{T}{2} - \tau(t) \leq \frac{T}{2}\) we have

\[
2\zeta^T(t)PDF(t)E_1z(t) \leq \zeta^T(t)[\epsilon_1PDD^T P + \epsilon_1^{-1}E_1^T E_1]z(t)
\]

\[
-2\zeta^T(t)PDF(t)E_1A_1 \int_{t-T/2}^{t} x(s)ds \leq \frac{T}{2} \zeta^T(t)\epsilon_1PDD^T Pz(t)
\]

and

\[
2\zeta^T(t)PDF(t)E_2x(t) - \zeta^T(t)\epsilon_4PDD^T Pz(t) + \zeta^T(t)\epsilon_4^2K^T E_3E_2z(t)
\]

Thus, \(V_2(x_i)\) is positive definite.

Next, to prove the negative of time derivative of \(V(x_i)\), we will consider two cases.

First, we consider the case when \(\tau(t) < \frac{T}{2}\).

We rewrite (10) as

\[
\begin{align*}
\dot{V}(t) &= \dot{V}_1(x_i) + \dot{V}_2(x_i) \\
V_1(x_i) &= \int_{t-T/2}^{t} x^T(s)Qx(s)ds + \int_{t-T/2}^{t} \int x^T(v)Qx(v)dvds \\
V_2(x_i) &= \int_{t-T/2}^{t} \int x^T(v)Gx(v)dvds + \int_{t-T/2}^{t} \int x^T(s)Gx(s)ds \]
\end{align*}
\]

Thus, \(V_2(x_i)\) is positive definite. Moreover, \(V_1(x_i)\) and \(V_2(x_i)\) are continuously twice differentiable in \(x\) and once in \(t\).
and combining (14)-(21), we obtain

\[
2z^T(t)PA_1 \int (A_1 + \Delta A_1(s)) x(s - \tau(s))ds \leq \\
\frac{\mu}{2}z^T(t)PA_1 X_2 A_1^TPz(t)
\]

\[
+ \int z^T(s) (A_1 + \Delta A_1(s))^T X_2^{-1} (A_1 + \Delta A_1(s))x(s - \tau(s))ds,
\]

\[
\frac{\mu}{2}z^T(t)PA_1 X_2 A_1^TPz(t) + \int z^T(s) (B + \Delta B(s))^T X_3^{-1} (B + \Delta B(s))Kz(s)ds
\]

\[
(20)
\]

Defining

\[
\Sigma_i = (A_1 + \Delta A_1)^T P + P(A_1 + \Delta A_1) + \\
PBB + K^T B^T P + (\mathbf{e}_1 + \frac{\mu}{2} \mathbf{e}_2 + \mathbf{e}_3 + \mathbf{e}_4)PDD^T P
\]

\[+ \mathbf{e}_1^T E_1^T E_1 + \mathbf{e}_2^T K^T E_2^T E_2 K
\]

\[+ \frac{\mu}{2}PA_1 (X_1 + X_2 + X_3) A_1^TP
\]

and combining (14)-(21), we obtain

\[
\dot{V}_1(x(t)) \leq z^T(t) \Sigma_1 z(t)
\]

\[
- 2z^T(t)PA_1 \int \frac{t}{2} x(s)ds
\]

\[+ x^T(t - \tau(t)) \mathbf{e}_3^T E_2^T E_2 x(t - \tau(t))
\]

\[+ \int z^T(s) \mathbf{e}_2^T A_1^T E_1^T E_1 A_1 x(s)ds
\]

\[+ \int z^T(s)(A_1 + \Delta A_1(s))^T X_2^{-1} (A_1 + \Delta A_1(s))x(s)ds
\]

\[
\frac{\mu}{2}z^T(t)PA_1 X_2 A_1^TPz(t) + \int z^T(s) (B + \Delta B(s))^T X_3^{-1} (B + \Delta B(s))Kz(s)ds
\]

\[
(21)
\]

Combining (22), (23) and (24), we obtain

\[
\dot{V}_1(x(t)) = \dot{V}_2(x(t)) + \dot{V}_3(x(t))
\]

\[\leq z^T(t) \Sigma_1 T_1 \Sigma_1 T_1 z(t)
\]

\[+ \int z^T(s)(B + \Delta B(s))^T X_3^{-1} (B + \Delta B(s))Kz(s)ds
\]

\[
(22)
\]

At this point, we have obtained (25) when \( \tau(t) < \frac{\mu}{2} \).

On the other hand, using a similar analysis method, we can obtain that when \( \tau(t) \geq \frac{\mu}{2} \),

\[
\dot{V}_2(x(t)) \leq x^T(t) \hat{T}_x(t) - (1 - d)x^T(t)(t - \tau(t))Tx(t - \tau(t))
\]

\[
- \int x^T(s)Qx(s)ds + \int x^T(s)Gx(s)ds
\]

\[+ \int x^T(s)Wx(s)ds + \int x^T(s)Rz(s)ds,
\]

\[
(23)
\]

where \( T_1 = T + \frac{\mu}{2}Q + \frac{\mu}{2}G + \frac{\mu}{2(1 - d)}W \). In addition, using (8), we can prove that

\[
x^T(t)(t - \tau(t)) \leq z^T(t) \Sigma_1 T_1 \tau(t) - 2z^T(t)T_1 A_1 \int \frac{t}{2} x(s)ds
\]

\[+ \int z^T(s)T_1 A_1 x(s)ds.
\]

Combining (22), (23) and (24), we obtain

\[
\dot{V}(x(t)) = \dot{V}_1(x(t)) + \dot{V}_2(x(t)) + \dot{V}_3(x(t))
\]

\[
\leq \dot{z}^T(t) \Sigma_1 T_1 \tau(t) + \dot{z}^T(t)\dot{z}(t)
\]

\[
- \int \dot{z}^T(t)(t - \tau(t))(1 - d)t - \dot{z}^T(t)T_1 A_1 \int \frac{t}{2} x(s)ds
\]

\[+ \int \dot{z}^T(s)T_1 A_1 x(s)ds.
\]

(24)

At this point, we have obtained (25) when \( \tau(t) < \frac{\mu}{2} \).

On the other hand, using a similar analysis method, we can obtain that when \( \tau(t) \geq \frac{\mu}{2} \),

\[
\dot{V}(x(t)) = \dot{V}_1(x(t)) + \dot{V}_2(x(t)) + \dot{V}_3(x(t))
\]

\[
\leq \dot{z}^T(t) \Sigma_1 T_1 \tau(t) + \dot{z}^T(t)\dot{z}(t)
\]

\[
- \int \dot{z}^T(t)(t - \tau(t))(1 - d)t - \dot{z}^T(t)T_1 A_1 \int \frac{t}{2} x(s)ds
\]

\[+ \int \dot{z}^T(s)T_1 A_1 x(s)ds.
\]

(26)

From (25) and (26), it is easy to see that if \(-G + (A + \Delta A(s))^T X_1^{-1} (A + \Delta A(s)) < 0 \),

(27)
Using Lemma 1, it can be shown that (27), (28) and (29)

\[ T = \xi_1(1-d)^{-1}E_2^TE_2 \]

then

\[ \dot{V}(x) \leq \frac{1}{2} \int_{t-\tau/2}^t \left[ z^T(t) x^T(s) H \right] ds \]

where

\[
H = \begin{bmatrix}
\Sigma + \tau + \tau - \frac{1}{2} \Sigma A + A \Sigma A - \frac{1}{2} \tau I_A & H^T \\
\tau^2 + \tau - \frac{1}{2} \Sigma A + A \Sigma A & H^T \\
\tau^2 + \tau - \frac{1}{2} \Sigma A + A \Sigma A & H^T
\end{bmatrix}
\]

Obviously, if \( H < 0 \) holds, then there exists a constant \( \lambda > 0 \) such that

\[ \dot{V}(t, x) < -\lambda x^T(t) x(t) \]

Next, we will prove that (4), (5), (6) and (7) implies \( H < 0 \), (27), (28) and (29).

Using Schur complements, it can be shown that

\[
H = \begin{bmatrix}
\Sigma + \tau + \tau - \frac{1}{2} \Sigma A + A \Sigma A - \frac{1}{2} \tau I_A & H^T \\
\tau^2 + \tau - \frac{1}{2} \Sigma A + A \Sigma A & H^T \\
\tau^2 + \tau - \frac{1}{2} \Sigma A + A \Sigma A & H^T
\end{bmatrix} < 0
\]

\[
H^T = \begin{bmatrix}
\Sigma + \tau + \tau - \frac{1}{2} \Sigma A + A \Sigma A - \frac{1}{2} \tau I_A & H^T \\
\tau^2 + \tau - \frac{1}{2} \Sigma A + A \Sigma A & H^T \\
\tau^2 + \tau - \frac{1}{2} \Sigma A + A \Sigma A & H^T
\end{bmatrix}
\]

\[
M_1 = diag\left(1-d^2 \xi_1, \frac{1}{2} \tau_1, \frac{1}{2} \tau_2 \right).
\]

Pre, post-multiplying the both sides of (33) with matrix \( diag\left(1-d^2 \xi_1, \frac{1}{2} \tau_1, \frac{1}{2} \tau_2 \right) \)

\[ \dot{V}(t, x) < -\lambda x^T(t) x(t) \]

where

\[
\xi_1 = X(A + A_1)^T + (A + A_1)X + BY + Y^T B^T + (\xi_1 + \xi_2 + \xi_3)D + \xi_1^T X E_1 Y + \xi_1^T Y E_1 X + \xi_2^T Y E_1 X + \xi_3^T Y E_1 X
\]

\[
M_2 = diag\left(1-d^2 \xi_1, \frac{1}{2} \tau_1, \frac{1}{2} \tau_2 \right).
\]

Using Lemma 1, it can be shown that (27), (28) and (29) hold if the following matrix inequalities hold

\[
-G + A^T (X_1 - \xi_3 D) E_1^T E_1 < 0, \quad (35)
\]

\[
-(\xi_1 + \xi_3) D + \xi_3^T E_1 E_1 < 0, \quad (36)
\]

\[
-G + A^T (X_2 - \xi_3 D) E_1^T E_2 < 0, \quad (37)
\]

using transformations \( Y = KX \), \( Y_1 = G \), \( Y_2 = W \) and

\[ Y_4 = P^{-1}(R P)^{-1}, \quad (35), (36) \text{ and } (37) \text{ can be written as}
\]

\[
y_2 + y_2 A^T (X_1 - \xi_3 D) E_1^T E_1 Y_2 < 0, \quad (38)
\]

\[
y_3 + y_3 A^T (X_2 - \xi_3 D) E_1^T E_2 Y_2 < 0, \quad (39)
\]

\[
y_4 + y_4 B^T (X_3 - \xi_3 D) E_2^T E_2 Y_2 < 0, \quad (40)
\]

By Schur complements, we can show that (36), (38), (39) and (40) are equivalent to (4), (5), (6) and (7), respectively. In other words, (4), (5), (6) and (7) are sufficient conditions that guarantee \( H < 0 \), (27), (28) and (29).

On the other hand, by Schur complements, \( H < 0 \) also means

\[ -Q + \frac{1}{4} A^T Q A < 0 \]

By Schur complements and matrix theory, we can further prove that a positive scalar \( 0 < \alpha < 1 \) exists such that

\[
\begin{bmatrix}
\alpha Q & -\frac{1}{4} A^T Q A \\
\frac{1}{4} A^T Q A & -Q
\end{bmatrix} \leq 0.
\]

Using Lemma 2, we know that under the condition (41), \( z(t) \) is a stable operator. Then, combining (32) and using Theorem 9.8.1 of (Hale, J., et al., 1993), we can complete our proof.

Q.E.D

**Remark**: For a given \( d \), the largest \( \tau \), which ensures the robust stabilization, can be determined by solving a convex optimization problem (Boyd, S., et al., 1994). Moreover, it can be found from (3) that only upper bound of the time delay is needed to implement the controller (3) although the controller has feedback of the current state and the past state information.

### 3. Example

**Example 1**: Consider the following system (Carlos E. De Souza, et al., 1999)

\[
\dot{x}(t) = \left[A + \Delta A(t)\right]x(t) + \left[A_1 + \Delta A_1(t)\right](x(t - \tau(t))) + Bu(t),
\]

where

\[
A = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}, \quad A_1 = \begin{bmatrix} -1 & -1 \\ 0 & -0.9 \end{bmatrix}, \quad B = \begin{bmatrix} 0 \\ 1 \end{bmatrix},
\]

\[
\|A_1(t)\| \leq 0.2 \quad \text{and} \quad \|A_1(t)\| \leq 0.2 \quad \text{at} \; \tau(t) \leq 0.1.
\]

\( \tau(t) \) satisfies

\[ 0 \leq \tau(t) \leq \tau \text{ and } \tau(t) \leq d < 1. \]

Choose \( D_1 = D_2 = \begin{bmatrix} 0.2 & 0 \\ 0 & 0.2 \end{bmatrix}, \quad E_1 = E_2 = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}. \)

In (Carlos E. De Souza, et al., 1999), it was shown that the maximum allowable value of \( \tau \) that guarantees
the system (43) with $d = 0$ is stable via a memoryless controller is 0.3346. However, by applying Theorem 1, we found that the upper bound of $\tau$ which guarantees (43) with $d = 0$ is stable via the controller (3) is 0.5492. In other words, we can design a controller as

$$u(t) = -0.2132 \int_{t-0.2542}^{t} x(s) ds + 0.11046 \int_{t-0.2542}^{t} x(s) ds,$$

which guarantees that the closed-loop system is asymptotically stable for any $\tau \in [0, 0.5492]$. If $d = 0.5$, the upper bound of $\tau$ which guarantees (43) is stable via the controller (3) is 0.3927. If $d = 0.9$, the upper bound of $\tau$ is 0.1298.

**Example 2:** Consider the following system (Li Xi., et al., 1997)

$$\dot{x}(t) = \begin{bmatrix} A + \Delta A(t) \end{bmatrix} x(t) + \begin{bmatrix} A_1 + \Delta A_1(t) \end{bmatrix} x(t - \tau) + Bu(t),$$

where $A = \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}$, $A_1 = \begin{bmatrix} -2 & -0.5 \\ 0 & -1 \end{bmatrix}$, $B = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$.

$\|\Delta A(t)\| \leq 0.2$ and $\|\Delta A_1(t)\| \leq 0.2$. $\tau(t)$ satisfies $0 \leq \tau(t) \leq \bar{\tau}$ and $\tau(t) \leq d < 1$.

Choose $D_1 = D_2 = \begin{bmatrix} 0.2 & 0 \\ 0 & 0.2 \end{bmatrix}$, $E_1 = E_2 = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$.

In , it was shown that the maximum allowable value of $\tau$ that guarantees the system (44) with $d = 0$ is stable via a memoryless controller is 0.3015. However, by applying Theorem 1, we found that the upper bound of $\tau$ which guarantees (44) is stable via the controller (3) is 0.5084. In other words, we can design a controller as

$$u(t) = -0.2521 \int_{t-0.2542}^{t} x(s) ds + 101.7509 \int_{t-0.2542}^{t} x(s) ds,$$

which guarantees that the closed-loop system is asymptotically stable for any $\tau \in [0, 0.5084]$.

If $d = 0.5$, the upper bound of $\tau$ which guarantees (44) is stable via the controller (3) is 0.3858. If $d = 0.9$, the upper bound of $\tau$ is 0.1538.

4. CONCLUSIONS

In this paper, a robust controller with delay compensation was proposed for uncertain systems with time varying delay based on the Lyapunov function method. Like the memoryless controller case, it is not required to know the exact value of the time delay although the designed controller in this paper depends on the current state and past state information. Since more information on the state is used, the given controller can achieve a better performance than memoryless controllers in the existing references.
