Abstract: An adaptive neural network controller is proposed to deal with the end-effector tracking problem of manipulators with uncertainties. By employing the adaptive Jacobian scheme, neural networks, and backstepping technique, the torque controller can be obtained which is demonstrated to be stable by the Lyapunov approach. The updating laws for designed controller parameters are derived by the projection method, and the tracking error can be reduced as small as possible. The favorable features of the proposed controller lie in that: (1) the uncertainty in manipulator kinematics is taken into account; (2) the “linearity-in-parameters” assumption for the uncertain terms in dynamics of manipulators is no longer necessary; (3) effects of external disturbances are considered in the controller design. Finally, the satisfactory performance of the proposed approach is illustrated by simulation results on a PUMA 560 robot.

1. INTRODUCTION

In the past decades, robust adaptive motion control has been thoroughly studied to counteract uncertainties in the robot dynamics (see surveys Ortega and Spong [1989], Abdallah et al. [1991]). However, in most applications, the manipulator end-effector is required to track a given trajectory in the task space. The kinematics of robot manipulators is commonly assumed known exactly to achieve this control objective. Unfortunately, due to the imprecise measurement of physical parameters and the interaction between robot and different environments, the kinematic parameters cannot be known a priori. Therefore, uncertainty in the robot kinematic model is a practical problem.

There are relatively few articles to address this topic. As reported by Arimoto [1999], the research on the control problem with uncertain kinematics is just a beginning. Cheah et al. [1999] first proposed an approximation Jacobian method to overcome kinematic uncertainties. Based on this method, Cheah et al. [2003] also suggested a hybrid position and force controller when the interaction between the manipulator end-effector and environments was considered. Dixon [2007] presented an amplitude limited controller and eliminated the bounded mismatch assumption for estimated Jacobian. However, above results are focusing on the regulation control of robot. As to tracking control problems, Cheah et al. [2004] studied an adaptive Jacobian approach for trajectory tracking of non-redundant robot with uncertain kinematics and dynamics. Extensions to the redundant robot and uncertain actuator parameters were done by Cheah et al. [2006]. It is noted that aforementioned controllers employ the standard adaptive control scheme to compensate effects of gravity and other terms.

in the manipulator dynamics, which means that they will suffer from the “linearity-in-parameters” assumption and the tedious analysis of determining “regression matrices”. In addition, the surface friction and external disturbance in robot dynamics have been neglected in the controller design.

Recently, neural networks have been successfully used for the nonlinear system identification and control due to the “universal approximation” property [Liu, 2001]. Several neural-network-based adaptive controllers are also presented to eliminate the “linearity-in-parameters” assumption in standard adaptive control (see Farrell and Polycarpou [2006] for the general framework of these methods). An attractive feature of these methods is that synaptic weights of neural networks are tuned on-line without any off-line learning phases. In literature, some adaptive neural network controllers have been proposed for the tracking control of robot manipulators by Lewis et al. [1998], Ge et al. [1998]. However, these controllers are designed to move robots along the desired joint angles, the manipulator kinematics is not taken into account.

This paper addresses the end-effector tracking problem of robot manipulators with uncertain kinematics and dynamics. By using adaptive Jacobian method, neural network approximation, and backstepping technique, an adaptive neural network controller is obtained. The adaptive updating laws for controller parameters are derived by the projection method. Stability of the proposed controller is guaranteed by the Lyapunov theory. And the tracking error can be reduced as small as possible. Compared with controller used in Cheah et al. [2004], the “linearity-in-parameters” assumption for the manipulator dynamics is no longer necessary, external disturbances and surface frictions are taken into account, and the velocity of robot end-effector is not required.
2. MATHEMATICAL PRELIMINARIES

Let \( \| \cdot \| \) denote any suitable vector norm. When it is required to be specific, \( \| \cdot \|_p \) denotes the \( p \)-norm of given vector. The Frobenius norm of matrix \( A = [a_{ij}] \in \mathbb{R}^{n \times m} \) is defined by
\[
\| A \|_F^2 = \text{Tr} \left( A^T A \right) = \text{Tr} \left( AA^T \right) = \sum_{i,j} a_{ij}^2,
\]
where \( \text{Tr}(\cdot) \) represents the trace operator. The Frobenius norm is compatible with the 2-norm such that \( \| Ax \|_2 \leq \| A \|_F \| x \|_2 \) with \( A \in \mathbb{R}^{n \times m} \) and \( x \in \mathbb{R}^m \). The trace operator has the following useful property, that is
\[
a^T b = \text{Tr} \left( ab^T \right),
\]
where \( \forall a, b \in \mathbb{R}^n \).

2.1 Kinematics and Dynamics of Robot Manipulators

Consider a rigid \( n \)-link, serially connected robot manipulator. Let \( x \in \mathbb{R}^m \) represent a task-space vector which is related to the robot joint vector \( q \in \mathbb{R}^n \) as
\[
x = h(q),
\]
where \( h(q) \in \mathbb{R}^m \) is the differentiable forward kinematics of the manipulator. The task-space velocity \( \dot{x} \) is related to the joint-space velocity \( \dot{q} \) as
\[
\dot{x} = J(q, \dot{q}) \dot{q},
\]
where \( J(q, \dot{q}) \in \mathbb{R}^{m \times n} \) represents the kinematic parameters of robot manipulators, such as link lengths and joint offsets; \( J(q, \dot{q}) \) is the Jacobian matrix which has the following property.

Property 1. The product of the manipulator Jacobian matrix with the joint velocity vector can be linearly parameterized as
\[
J(q, \dot{q}) \dot{q} = Y(q, \dot{q}) \dot{q},
\]
where \( Y(q, \dot{q}) \in \mathbb{R}^{m \times n} \) can be computed directly by the measurable joint position and velocity vectors \( q \) and \( \dot{q} \).

The dynamic model of robot manipulators can be expressed as [Lewis et al., 1998]
\[
M(q) \ddot{q} + V(q, \dot{q}) \dot{q} + F(q) + G(q) + \tau_{ed} = \tau,
\]
where \( \ddot{q}, q \in \mathbb{R}^n \) denotes the joint acceleration vector; \( M(q) \in \mathbb{R}^{n \times n} \) is the inertia matrix; \( V(q, \dot{q}) \in \mathbb{R}^{n \times n} \) is the centripetal-Coriolis matrix; \( F(q) \in \mathbb{R}^n \) denotes the surface friction; \( G(q) \in \mathbb{R}^n \) is the gravitational vector; \( \tau_{ed} \in \mathbb{R}^n \) denotes the bounded external disturbance vector including unstructured model dynamics; \( \tau \in \mathbb{R}^n \) represents the torque input vector. Two important properties of this dynamics formulation are given as follows [Lewis et al., 1998].

Property 2. The inertia matrix \( M(q) \) is symmetric and positive definite, and satisfies the following inequalities:
\[
m_1 \| y \|_2^2 \leq y^T M(q) y \leq m_2 \| y \|_2^2, \quad \forall y \in \mathbb{R}^n,
\]
where \( m_1 \) and \( m_2 \) are known positive constants.

Property 3. The time derivative of the inertia matrix and the centripetal-Coriolis matrix satisfy the skew symmetric relation; that is,
\[
x^T \left( M(q) - 2V(q, \dot{q}) \right) x = 0, \quad \forall x \in \mathbb{R}^n.
\]

Fig. 1. The structure of the two-layer neural network.

2.2 Multilayer Neural Networks

An attractive ability of neural networks for control purpose is that they can approximate any smooth nonlinear function up to a small error. In this paper, a two-layer neural network shown in Fig. 1 is employed as the function approximator. The output of two-layer neural network can be determined by the following formula [Lewis et al., 1998]
\[
y = W \sigma(V \hat{z}),
\]
where \( N_1, N_h \) and \( N_o \) denote the numbers of input-layer neurons, hidden-layer neurons and output-layer neurons, respectively; \( W \in \mathbb{R}^{N_o \times (N_h+1)}, V \in \mathbb{R}^{N_h \times (N_i+1)} \) are augmented weight matrices; \( \hat{z} = [1, z^T]^T = [1, z_1, z_2, \ldots, z_{N_h}]^T \) is augmented input vector; \( \sigma(V \hat{z}) = [\sigma(V_{1z}), \sigma(V_{2z}), \ldots, \sigma(V_{N_hz})]^T \) is the augmented activation function vector; \( V_{i1} \) represents the \( i \)th row of matrix \( V \). By this augmented expression, any tuning of \( W \) and \( V \) will include tuning of the thresholds \( \theta_{o1} \) and \( \theta_{i1} \) as well. In this paper, following sigmoid function is adopted as the activation function,
\[
\sigma(s) = \frac{1}{1 + e^{-s}}.
\]
Let \( S \) be a compact simply connected set of \( \mathbb{R}^{N_i} \), and \( g(z) \) be any smooth function from \( S \) to \( \mathbb{R}^{N_o} \). Then, it can be shown that, for any given positive constant \( \varepsilon_N \), there exist the ideal weight matrices \( W^* \) and \( V^* \) and the number of hidden layer neurons \( N_h \) such that
\[
g(z) = W^* \sigma(V^* \hat{z}) + \varepsilon,
\]
where \( \varepsilon \) is the bounded function approximation error satisfying \( |\varepsilon| < \varepsilon_N \) in \( S \).

It should be noted that the ideal matrices \( W^* \) and \( V^* \) are only quantities required for analytical purpose. For real applications, their estimations \( W \) and \( V \) are used for the practical function approximation. The estimation of \( g(z) \) can be given by
\[
\hat{g}(z) = \hat{W} \sigma(\hat{V} \hat{z}).
\]

Lemma 1. [Ge et al., 1999] For the neural network defined by (9), the function estimation error can be expressed as
\[
\hat{g}(z) - g(z) = \hat{W} \sigma(\hat{V} \hat{z}) - W^* \sigma(V^* \hat{z}) - \varepsilon
\]
\[
= W \left( \hat{\sigma} - \sigma \right) \hat{V} \hat{z} + \hat{W} \sigma' \hat{V} \hat{z} + d_u,
\]
where \( \hat{\sigma} = \sigma(\hat{V}z) \); \( \hat{\sigma}' = \text{diag}\{0, \hat{\sigma}'_1, \hat{\sigma}'_2, \ldots, \hat{\sigma}'_N\} \) with \( \hat{\sigma}'_i = d\sigma(s)/ds|_{s=\hat{V}r_i} \); the weight matrix estimation errors are \( \bar{W} = \hat{W} - W^* \) and \( \bar{V} = \hat{V} - V^* \); and the residual term is \( d_u = \hat{W}dV^*z + W^*O(V^*)^2 - \hat{e} \), which is bounded by
\[
\|d_u\| \leq c_0 + c_1\|\bar{x}\| + c_2\|\bar{W}\|\|x\|, \tag{11}
\]
where \( c_0, c_1 \) and \( c_2 \) are positive constants.

2.3 Stability of Systems

**Definition 1.** [Lewis et al., 1998] Given a nonlinear dynamical system
\[
\dot{x}(t) = f(x(t), x(t) \in \mathbb{R}^n, \ t \geq t_0.
\]
If there exists a compact set \( \mathcal{U}_x \in \mathbb{R}^n \) such that for all \( x(t_0) = \bar{x}_0 \in \mathcal{U}_x \), there exist a \( \delta > 0 \) and a number \( T(\delta, \bar{x}_0) \) such that \( \|x(t)\| \leq \delta \) for all \( t \geq t_0 + T \), then the solution of the nonlinear dynamical system is called uniformly ultimately bounded (UUB).

3. ADAPTIVE NEURAL NETWORK CONTROLLER

The control objective is to develop a task-space tracking controller for the end-effector of robot manipulators with uncertainties and external disturbances. Here, the backstepping approach is employed to achieve this control goal. The backstepping method designs partial Lyapunov functions and auxiliary controllers for each subsystem of the whole nonlinear system, and integrates these auxiliary controllers into the actual controller by “back stepping” through the system and reassembling it from its component subsystems [Kanellakopoulos et al., 1991].

First, a mild assumption, which always holds in practical applications, is stated as follows.

**Assumption 1.** Let \( x_d(t) \in \mathbb{R}^m \) denote the desired task-space trajectory. It is assumed that \( x_d(t) \) and its derivatives up to the second order are bounded in the sense, for instance, that
\[
\begin{align*}
\|x_d(t)\| &
\leq X_M, \\
\|\dot{x_d}(t)\| &
\leq X_M, \\
\|\ddot{x_d}(t)\| &
\leq X_M,
\end{align*}
\tag{12}
\]
where \( X_M \) is a known constant.

Define the tracking error \( e_1(t) \in \mathbb{R}^m \) as
\[
e_1 = x - x_d.
\tag{13}
\]
Differentiating \( e_1(t) \) obtains
\[
\dot{e}_1 = \dot{x} - \dot{x}_d = J(q, \phi)\dot{q} - \dot{x}_d.
\tag{14}
\]
In the presence of kinematic uncertainty, the parameter \( \phi_j \) in the Jacobian matrix \( J(q, \phi_j) \) is not known exactly. By replacing the uncertain parameter \( \phi_j \) with its estimation \( \hat{\phi}_j \), an approximate Jacobian \( \tilde{J}(\hat{q}, \hat{\phi}_j) \in \mathbb{R}^{m \times n} \) can be obtained.

The first step of backstepping design is to treat \( \hat{q} \) as an auxiliary control signal to the error dynamics defined by (14). This auxiliary signal is called as \( \hat{u} \) and chosen as
\[
\begin{align*}
\dot{\hat{q}} &= \tilde{J}^T(q, \hat{\phi}_j) (\hat{x}_d - K_1 e_1) + \\
&\quad (I_n - \tilde{J}^T(q, \hat{\phi}_j) \tilde{J}(q, \hat{\phi}_j)) \lambda,
\end{align*}
\tag{15}
\]
where \( \tilde{J}^T(q, \hat{\phi}_j) = J^T(q, \hat{\phi}_j) (J(q, \hat{\phi}_j) J^T(q, \hat{\phi}_j))^{-1} \) is the generalized inverse matrix of the approximate Jacobian matrix; \( K_1 \in \mathbb{R}^{m \times n} \) is a positive definite constant diagonal matrix; \( I_n \) is an \( n \)-dimensional unity matrix; \( \lambda \in \mathbb{R}^n \) is an auxiliary term which can be used for optimization purposes. It is assumed that the manipulator is operating in a finite task space such that the approximate Jacobian matrix is of full rank. This assumption is commonly adopted to deal with manipulator kinematic uncertainty in the existing literature [Cheah et al., 2004, 2006, Dixon, 2007]. Then the error dynamics defined by (14) can be rewritten as
\[
\begin{align*}
\dot{e}_1 &= (J(q, \phi_j) - \tilde{J}(q, \hat{\phi}_j)) \dot{\hat{q}} + \dot{\hat{J}}(q, \hat{\phi}_j) \hat{q} \\
&\quad + J(q, \phi_j) e_2 - \dot{x}_d \\
&= -K_1 e_1 + J(q, \phi_j) e_2 + Y_j(q, \dot{q}) (\dot{\phi}_j - \hat{\phi}_j) \\
&= -K_1 e_1 + J(q, \phi_j) e_2 - Y_j(q, \dot{q}) \hat{\phi}_j, \tag{16}
\end{align*}
\]
where \( e_2 = \hat{q} - \dot{\hat{q}} \). It is assumed that the uncertain parameter \( \phi_j \) in manipulator kinematics is bounded by the unknown upper limit \( \phi_j^u \) and lower limit \( \phi_j^l \), i.e., \( \phi_j^l \leq \phi_j(t) \leq \phi_j^u \), \( i = 1, 2, \ldots, p \), where \( (\cdot)_i \) denotes the ith element of given vector.

The second step is try to design the actual torque controller \( \tau \) which makes \( e_2 \) as small as possible. To achieve this, the error dynamics for \( e_2 \) is derived by (4)
\[
M(q) \dddot{e}_2 + V(q, \dot{q}) e_2 = \tau - M(q) \dddot{\hat{q}} - V(q, \dot{q}) \hat{q} - F(\hat{q}) - \tau_{ed} = \tau - f_1 - \tau_{ed}.
\tag{17}
\]
The torque controller \( \tau \) is chosen as
\[
\tau = \tilde{F}_1 - K_2 e_2 - \gamma_1, \tag{18}
\]
where \( K_2 \) is a diagonal positive definite gain matrix; \( \gamma_1 \) is a robustness signal which counteracts the approximation error and external disturbances in the second step. \( \tilde{F}_1 \) is the estimation of \( F_1 \) which is defined by
\[
F_1 = f_1 + J^T(q, \phi_j) e_1.
\tag{19}
\]
It is noted that the term \(-J^T(q, \phi_j) e_1 \) in \( F_1 \) is used to compensate the coupling term \( J(q, \phi_j) e_2 \) in (16). In the standard adaptive scheme, it has to assume that the uncertain term \( F_1 \) has the “linearity-in-parameters” property in order to obtain the adaptive updating law. However, this assumption does not hold if the friction \( F(\hat{q}) \) has the particular nonlinear form [Ge et al., 2001]. Motivated by the universal approximation ability of neural networks, a multilayer neural network is employed to learn the uncertain function \( F_1 \). By the previous introduction for the multilayer neural network, it can be obtained that, over a compact set,
\[
\tilde{F}_1 = W^*_1 \sigma(\bar{V}_1^T \bar{Z}_1) + e_1, \tag{20}
\]
with the approximation error \( e_1 \) and neural network input \( \bar{Z}_1 = [1, e^T_1, e^T_2, x^T_d, \dddot{x}^T_d] \). The estimation of \( F_1 \) is given by
\[
\tilde{F}_1 = \hat{W}_1 \sigma(\hat{V}_1^T \hat{Z}_1).
\tag{21}
\]
By Lemma 1, substituting (18), (19), (20) and (21) into (17) obtains that
\[
M(q) \dddot{e}_2 + V(q, \dot{q}) e_2 = -K_2 e_2 - \gamma_1 - f_1 - \tau_{ed} \tag{22}
\]

2384
where \( \hat{\sigma}_1 = \sigma(\hat{V}_1\bar{Z}_1); \hat{\sigma}'_1 = \sigma'(\hat{V}_1\bar{Z}_1); \delta_1 = -\tau_{ed} - \varepsilon_1 - \hat{W}_1\hat{\sigma}'_1\bar{Z}_1 - W_1^*O(\tilde{V}_1\bar{Z}_1)^2. \)

The robustness signal \( \gamma_1 \) takes the following hyperbolic tangent form

\[
\gamma_1 = \delta M_1 \tanh \left( \frac{2k_u\delta M_1 e_2}{\varepsilon_1} \right),
\]

where \( k_u = 0.2785, \varepsilon_1 \) is a positive design scalar, \( \delta M_1 \) is the upper bound of \( \delta_1 \) (By Lemma 1 and the stability result in the next section, it can be shown that \( \delta_1 \) is indeed bounded). It is easy to check that \( \gamma_1 \) has the following properties,

\[
e^T_2 \gamma_1 \geq 0, \quad \delta M_1 \|e_2\| - e^T_2 \gamma_1 \leq \varepsilon_1.
\]

By the projection algorithm, the adaptive updating laws for the kinematic parameter \( \hat{\phi}_J \) and neural network weight matrices \( \hat{W}_1 \) and \( \hat{V}_1 \) are derived as follows,

\[
\left( \dot{\hat{\phi}}_j \right) = \left( \begin{array}{l}
\beta_j (Y^T_j (q, \hat{q}_d)e_1)_j, & \text{if } (\hat{\phi}_j)_j \leq (\hat{\phi}_j)_j \\
0, & \text{otherwise}
\end{array} \right),
\]

for \( j = 1, 2, \ldots, p \).

\[
\dot{\hat{W}}_1 = e^T_2 \hat{W}_1 \left( \hat{\sigma}_1 - \sigma'_1\hat{V}_1 \bar{Z}_1 \right) \Gamma_{w1},
\]

\[
\dot{\hat{V}}_1 = -e_2^T \hat{W}_1 \left( \hat{\sigma}_1 - \sigma'_1\hat{V}_1 \bar{Z}_1 \right)_T \Gamma_{v1},
\]

where \( \beta_j \) is a given positive scalar; \( \Gamma_{w1} \) and \( \Gamma_{v1} \) are given positive constants for bounding neural network weight matrices; \( \Gamma_{w1} \) and \( \Gamma_{v1} \) are given positive definite diagonal matrices.

It is emphasized that the initial estimated kinematic parameter \( \hat{\phi}_J(0) \) should be selected as

\[
(\hat{\phi}_j)_j \leq (\phi^+_j)_j \leq (\hat{\phi}^-_j)_j,
\]

and the initial neural network weight matrices \( \hat{W}_1(0) \) and \( \hat{V}_1(0) \) satisfy that

\[
\begin{aligned}
\text{Tr} (\hat{W}_1(0)\Gamma_{w1}^{-1}\hat{W}_1^T(0)) &\leq W_{m1}, \\
\text{Tr} (\hat{V}_1(0)\Gamma_{v1}^{-1}\hat{V}_1^T(0)) &\leq V_{m1}.
\end{aligned}
\]

4. STABILITY ANALYSIS

**Theorem 1.** Given the robot manipulator defined by (2) and (4), if the controller is constructed as (18), the parameters updating laws are provided by (25), (26) and (27), and the initial values of estimated parameters satisfy the conditions (28) and (29), then \( e_1, e_2, \hat{\phi}_J, \hat{W}_1, W_1 \) and \( V_1 \) are all uniformly ultimately bounded signals.

**Proof.** According to the principle of projection algorithm, it is easy to check that \( \hat{\phi}_J \) is bounded by its upper and lower limitations. To prove the boundedness of \( \hat{W}_1 \), let \( L_{w1} = \text{Tr} (\hat{W}_1\Gamma_{w1}^{-1}\hat{W}_1^T) \).

By (26), it follows that

1. when \( L_{w1} = W_{m1} \) and \( e_2^T \hat{W}_1 \left( \hat{\sigma}_1 - \sigma'_1\hat{V}_1 \bar{Z}_1 \right) > 0, \)

\[
\frac{dL_{w1}}{dt} = 2 \text{Tr} (\hat{W}_1\Gamma_{w1}^{-1}\hat{W}_1^T) \]

is bounded by its upper and lower limitations. To prove the uniform ultimate boundedness of error signals \( e_1 \) and \( e_2 \), the following Lyapunov function is considered,

\[
V = \hat{V}_1 + V_2,
\]

where

\[
\hat{V}_1 = E^T_1 e_1 + \frac{1}{2} \hat{\phi}_J \Gamma_{\beta}^{-1} \hat{\phi}_J,
\]

\[
V_2 = \frac{1}{2} (e_2^T M(q)e_2 + \text{Tr} (\hat{W}_1\Gamma_{w1}^{-1}\hat{W}_1^T) + \text{Tr} (\hat{V}_1\Gamma_{v1}^{-1}\hat{V}_1^T)).
\]

By (16) and (25), deriving \( \hat{V}_1 \) with respect to time obtains that,

\[
\hat{V}_1 = e^T_1 K_1 e_1 + e^T_2 J(q, \hat{\phi}_J)e_2 - \hat{\phi}_J^T Y^T_j (q, \hat{\phi}_J)e_1 - \Gamma_{\beta}^{-1} \hat{\phi}_J.
\]

By (5), (22), (24) (26) and (27), the time derivative of \( V_2 \) is
\[ \dot{V}_2 = e_2^T M(q)e_2 + \frac{1}{2} e_2^T \dot{M}(q) e_2 + \text{Tr} \left( \dot{W}_1 \Gamma_{w1}^{-1} \dot{W}_1^T \right) \]

\[ + \text{Tr} \left( \dot{W}_1 \Gamma_{w1}^{-1} \dot{V}_1^T \right) \]

\[ \leq \text{Tr} \left( \dot{W}_1 \left( \sigma_1 - e_2^T \sigma_1 \dot{V}_1 \Gamma_{w1}^{-1} \dot{W}_1 \right) \right) + e_2^T K_2 e_2 - e_2^T J^T(q, \phi_J)e_1 \]

\[ + \text{Tr} \left( \dot{W}_1 \Gamma_{w1}^{-1} \dot{V}_1^T \right) \]

\[ + \text{Tr} \left( \dot{W}_1 \Gamma_{w1}^{-1} \dot{V}_1^T \right) + \|e_2^T \|\|\dot{\alpha}_1\| - e_2^T \gamma_1 \]

\[ \leq \text{Tr} \left( \dot{W}_1 \left( Z e_2^T \dot{W}_1 \sigma_1 + \Gamma_{w1}^{-1} \dot{V}_1^T \right) \right) + e_1 - e_2^T J^T(q, \phi_J)e_1 \]

\[ + \text{Tr} \left( \dot{W}_1 \left( \sigma_1 - e_2^T \sigma_1 \dot{V}_1 \right) \right) + e_2^T K_2 e_2 \]

\[ = e_2^T \dot{\rho}_2 \sigma_1 + e_2^T K_2 e_2 - e_2^T \rho_2 J^T(q, \phi_J)e_1 + e_1 \]

\[ = -\rho_2 K e + e_1 \]

\[ \leq -\lambda_{\min}(K) \|e\|^2 + e_1. \]  

Therefore, \( \dot{V} \) is strictly negative outside the following compact set \( \sum_c \).

\[ \sum_c = \left\{ \left[ e(t) \right| 0 \leq \|e(t)\| \leq \sqrt{\frac{e_1}{\lambda_{\min}(K)}} \right\}. \]  

According to the Lyapunov theory extension [Lewis et al., 1998], this demonstrates that \( e_1, e_2 \) are both uniformly ultimately bounded signals. And it is easy to see that \( e_1, e_2 \) can be reduced as small as possible by choosing appropriate \( K \) and \( \epsilon_1 \).

### 5. SIMULATION EXAMPLE

Computer simulations based on the Unimation PUMA 600 robot arm is conducted to demonstrate the effectiveness of the proposed controller. The mechanical configuration and coordinate system are given by Corke and Armstrong-Helouvry [1994]. The initial joint configuration of PUMA 600 is \( \varphi = [0, 0, 0, 0, 0, 0]^T \) rad and \( \dot{\varphi} = [0, 0, 0, 0, 0, 0]^T \) rad/s. Table 1 gives the Denavit and Hartenberg parameters of the PUMA 600 manipulator, where link length \( a_2 = 0.4318m, a_3 = 0.0203 m \) and joint offset \( d_3 = 0.15005 m, d_4 = 0.4318m \). \( \alpha_2, \alpha_3, d_3 \) and \( d_4 \) are the uncertain kinematic parameters. In the proposed controller, they are estimated initially as \( \hat{a}_2(0) = \hat{a}_3(0) = \hat{d}_3(0) = \hat{d}_4(0) = 0.1m \). The upper and lower limitations of the estimated parameters are \([0.5, 0.5, 0.5, 0.5]^T \) and \([0, 0, 0, 0]^T \). The initial position of PUMA 600 end-effector is specified as \( x(0) = (0.4521, -0.1500, 0.4318)^T \). The PUMA 600 end-effector is required to follow a prespecified straight line given by

\[ x_d(1) = 0.01t + 0.4021, \]
\[ x_d(2) = 0.03t - 0.2001, \]
\[ x_d(3) = 0.02t + 0.3818. \]

Because the last three joints, \( q_4, q_5 \) and \( q_6 \), do not contribute to the position of manipulator end-effector, there is no need to consider them in the controller design procedure. In this simulation, the position of hidden neurons is \( 60; \) parameters of controller are set that \( K_1 = \text{diag}(5, 5, 5); K_2 = \text{diag}(50, 50, 50); \lambda = 0; \tau_{\text{ad}} = \text{5 cos}(\pi t / 2), 4 \sin(\pi t / 2) + e^{-t}, \cos(t) + 3 \sin(\pi t / 3))^T; \Gamma_0 = \text{diag}(2, 2, 2, 2); N_h = 60; \psi(0) \) and \( \bar{V}(0) \) are set to be zero matrices; \( W_{\text{init}} = V_{\text{init}} = 1000; \psi_{\text{init}} = 20, \epsilon_1 = 0.1. \) The simulation results are shown in Figs. 2-4, which verifies the satisfactory tracking performance of the proposed controller.

### 6. CONCLUSION

A neural-network-based adaptive controller is proposed to deal with the manipulator task-space tracking problem. The proposed controller eliminates the "linearity-in-
parameters’ assumption for the uncertain terms in manipulator dynamics, avoids the tedious computation of regression matrix, and considers the external disturbance. The good control performance can be demonstrated by the Lyapunov approach and illustrated by the simulation example. Finally, by the cascade backstepping design procedure, the proposed controller can also be extended to the cases where the uncertain actuator model or the flexible joint manipulator are considered.
