Distributed Tracking of Multi-Agent Systems with High-Order Stochastic Nonlinear Dynamics *

Wuquan Li ∗ Ji-Feng Zhang ∗

∗ Key Laboratory of Systems and Control, Institute of Systems Science, Academy of Mathematics and Systems Science, Chinese Academy of Sciences, Beijing 100190, China (e-mail: sea81@126.com (W.Q. Li); jf@iss.ac.cn (J.F. Zhang)).

Abstract: The distributed tracking problem is investigated for a class of multi-agent systems with high-order stochastic nonlinear dynamics where the subsystem of each agent is driven by inherent nonlinear drift and diffusion terms. For the case where the graph topology is directed and the leader is the neighbor of only a small portion of followers, a new distributed integrator backstepping design method is proposed, and distributed tracking control laws are designed to ensure that the closed-loop system has an almost surely unique solution on $[0, \infty)$, all the states of the closed-loop system are bounded in probability, and the tracking errors can be tuned to arbitrarily small with a tunable exponential convergence rate. The efficiency of the tracking controller is demonstrated by a simulation example.

Keywords: High-order stochastic nonlinear; distributed integrator backstepping; multi-agent systems; directed graph topology.

1. INTRODUCTION

Research on distributed tracking of networked cooperative systems has attracted much attention in the past two decades due to their wide practical applications in areas such as large scale robotic systems (Belta and Kumar (2002)) and biological systems (Olfati-Saber (2006)). The main task of the distributed tracking is to drive the states of the followers to converge to those of a time-varying leader in the circumstance where only a portion of the followers has access to the leader’s states and the followers have only local interactions. For this kind of problems, Zhu and Cheng (2010) considers the case with time-varying delays in autonomous agents. Ma et al. (2010) considers the case with noises in communication channels. Lou et al. (2012) considers the case with switching topology.

Since all physical systems are nonlinear in nature (Khalil (2002)), it is necessary and beneficial to study the distributed problem in a network of nonlinear dynamical systems. Shi and Hong (2009) considers global target aggregation and state agreement of nonlinear multi-agent systems with switching topologies. Song et al. (2010) presents a pinning control and achieves leader-following consensus for multi-agent systems described by nonlinear second-order dynamics. Yu et al. (2011) investigates the consensus issue for the case where the nonlinear intrinsic function is Lipschitz and the directed network is generalized algebraically connected. Meng et al. (2013) studies the distributed robust cooperative tracking problem for multiple non-identical second-order nonlinear systems with bounded external disturbances.

Although some progress has been made towards cooperative tracking control of nonlinear multi-agent systems, the existing literature often assumes a simplified system model such as single integrators or double integrators. Also, there are very few results considering stochastic noise. This limits the validity of the models, since stochastic nonlinear systems are ubiquitous in practice. Thus, it is important for us to consider the distributed tracking problem of multi-agent systems with stochastic nonlinear dynamics.

In this paper, the distributed tracking problem of multi-agent systems with high-order stochastic nonlinear dynamics is investigated under a directed graph topology. By using the algebra graph theory and stochastic analysis method, distributed controllers are designed to ensure that the tracking error converges to an arbitrarily small pre-given neighborhood of zero. The main contributions of this paper include:

(1) A new distributed integrator backstepping design is proposed to effectively deal with the interactions among agents and coupling terms in dynamics;

(2) The systems investigated is high-order, stochastic and with inherent nonlinear drift and diffusion terms. Compared with the available results about nonlinear multi-agent systems such as Shi and Hong (2009), Song et al. (2010), Meng et al. (2013) and Zhang and Frank (2012),
the system model investigated is much more general and practical;
(3) The distributed controllers are designed to ensure that the tracking error exponentially converges to an arbitrarily pre-given small neighborhood of zero. The bound of tracking errors and the convergence rate can be explicitly given.

The remainder of this paper is organized as follows. Section 2 is on notation. Section 3 is for problem formulation. Section 4 presents a distributed integrator backstepping design method. Section 5 analyzes the performance properties of the closed-loop systems. Section 6 gives a numerical example to show the effectiveness of the theoretical results. Section 7 includes some concluding remarks.

2. NOTATION

The following notation will be used throughout the paper. For a given vector or matrix $X$, $X^T$ denotes its transpose. $\|X\|$ denotes its trace when $X$ is square, and $|X|$ is the Euclidean norm of a vector $X$. Let $\mathcal{G} = (\mathcal{V}, \mathcal{E}, A)$ be a weighted digraph of order $n$ with the set of nodes $\mathcal{V} = \{1, 2, \cdots, n\}$, set of arcs $\mathcal{E} \subset \mathcal{V} \times \mathcal{V}$, and a weighted adjacency matrix $A = (a_{ij})_{n \times n}$ with nonnegative elements. $(j, i) \in \mathcal{E}$ means that agent $j$ can directly send information to agent $i$. In this case, $j$ is called the parent of $i$, and $i$ is called the child of $j$. The set of neighbors of vertex $i$ is denoted by $\mathcal{N}_i = \{j \in \mathcal{V} : (j, i) \in \mathcal{E}, i \neq j\}$. $a_{ij} > 0$ if node $j$ is a neighbor of node $i$ and $a_{ij} = 0$ otherwise. In this paper, we assume that there is no self-loop, i.e., $a_{ii} = 0$. Node $i$ is called an isolated node, if it has neither parent nor child. Node $i$ is called a source if it has no parents but children. Denote the sets of all sources and isolated nodes in $\mathcal{V}$ by $\mathcal{V}_s = \{j \in \mathcal{V} : \mathcal{N}_j = \emptyset, \emptyset \}$ is the empty set). To avoid the trivial cases, $\mathcal{V} - \mathcal{V}_s \neq \emptyset$ is always assumed in this paper. A sequence $(i_1, i_2), (i_2, i_3), \cdots, (i_{k-1}, i_k)$ of edges is called a directed path from node $i_1$ to node $i_k$. A directed tree is a digraph, where every node except the root has exactly one parent and the root is a source. A spanning tree of $\mathcal{G}$ is a directed tree whose node set is $\mathcal{V}$ and whose edge set is a subset of $\mathcal{E}$. The diagonal matrix $D = diag(k_1, k_2, \cdots, k_n)$ is the degree matrix, whose diagonal elements $k_i = \sum_{j \in \mathcal{N}_i} a_{ij}$. The Laplacian of a weighted digraph $\mathcal{G}$ is defined as $L = D - A$.

We consider a system consisting of $n$ agents and a leader (labeled by 0) which is depicted by a graph $\mathcal{G}_0 = (\mathcal{V}_0, \mathcal{E}_0)$, where $\mathcal{V}_0 = \{0, 1, 2, \cdots, n\}$, set of arcs $\mathcal{E}_0 \subset \mathcal{V}_0 \times \mathcal{V}_0$. If $(0, i) \in \mathcal{E}_0$, then $0 \in \mathcal{N}_i$. A diagonal matrix $B = diag(b_1, b_2, \cdots, b_n)$ is the leader adjacency matrix associated with $\mathcal{G}_0$, where $b_i > 0$ if node 0 is a neighbor of node $i$; and $b_i = 0$, otherwise.

Definition 1 (Krstić and Deng (1998)). A stochastic process $x(t)$ is said to be bounded in probability if $|x(t)|$ is bounded in probability uniformly in $t$, i.e.,

$$\lim_{t \to \infty} \sup_{t > t_0} P\{|x(t)| > \epsilon\} = 0.$$
Theorem 1: If Assumption 3 holds, then, for $i = 1, \cdots, N$, $d_i = b_i + \sum_{s=1}^{N} a_{is} > 0$.

Proof: By Assumption 3 and the definition of spanning tree, one can get the conclusion easily.

With the help of Lemma 1, we have the following theorem.

**Theorem 1**: For $i = 1, \cdots, N$, $j = 2, \cdots, n_i$, let

$$
\xi_{i1} = \sum_{s=1}^{N} a_{is} (y_i - y_s) + b_i (y_i - y_0), \quad \xi_{ij} = x_{ij} - x_{ij}^*,
$$

$$
x_{ij}^* = -\xi_{i,j-1} \rho_{i,j-1} (\Lambda_{i,j-1}) + \frac{1}{d_i} \sum_{s=1}^{N} a_{is} x_{sj},
$$

and $V_{i,n_i} = \frac{1}{4} \sum_{j=1}^{n_i} \xi_{ij}^2$. Then, under Assumptions 1-3 we have

$$
\mathcal{L} V_{i,n_i} \leq - \sum_{j=1}^{n_i} (c_{ij} - \delta_{i,n_i} \bar{\sigma}) \xi_{ij}^4 + \xi_{i,n_i}^2 (\rho_{i,n_i} (\Lambda_{i,n_i})),
$$

$$
- \frac{1}{d_i} \sum_{s=1}^{N} a_{is} u_s + \sum_{s=1}^{n_i} \beta_s,
$$

where $c_{ij} > 0$, $j = 1, \cdots, n_i$, are design parameters; $\delta_{i,n_i} > 0$ and $\beta_s > 0$ are constants, $j = 1, \cdots, n_i - 1$, $s = 1, \cdots, n_i$; $\rho_{i,n_i} (\Lambda_{i,n_i})$ is a non-negative smooth function to be designed later, $\Lambda_{i,j} = (x_{i1}, \cdots, x_{iN}, x_{1j}, \cdots, x_{Nj})^T$.

Proof: By Assumption 3 and Lemma 1, one can see that (2) is well-defined.

The proofing of Theorem 1 proceeds step by step. Due to the limit of space, we only give the outline of the proof process:

Step 1. We firstly construct a distributed virtual controller $x_{i2}$ for the $\xi_{i1}$-subsystem;

Step 2. We now construct a distributed virtual controller $x_{i3}$ for the $\xi_{i2}$-subsystem, where $\xi_{i2} = (\xi_{i1}, \xi_{i2})^T$;

**Deductive Step.** At this step, we aim to construct a distributed virtual controller $x_{i1,k+1}^*$ for the $\xi_{i1}$-subsystem, where $\xi_{ik} = (\xi_{i1}, \xi_{i2}, \cdots, \xi_{ik})^T$;

Step $n_i$. We are now in a position to get (3) by analyzing the $\xi_{i,n_i}$-subsystem, where $\xi_{i,n_i} = (\xi_{i1}, \xi_{i2}, \cdots, \xi_{i,n_i})^T$.

Let

$$
M = \begin{bmatrix}
  1 - \frac{1}{d_1} a_{11} & - \frac{1}{d_1} a_{12} & \cdots & - \frac{1}{d_1} a_{1N} \\
  \vdots & \ddots & \ddots & \vdots \\
  \frac{1}{d_N} a_{N1} & - \frac{1}{d_N} a_{N2} & \cdots & 1 - \frac{1}{d_N} a_{NN}
\end{bmatrix}.
$$

To complete the design of the distributed control laws, the invertibility of the matrix $M$ should be firstly proved in the following Lemma.

**Lemma 2**: If Assumption 3 holds, then $M$ is an invertible matrix.

Based on Theorem 1 and Lemma 2, the distributed control laws are explicitly given in the following Theorem.

**Theorem 2**: Under Assumptions 1-3, if the distributed control laws are chosen as

$$
\begin{bmatrix}
  u_1 \\
  \vdots \\
  u_N
\end{bmatrix} = - M^{-1} \begin{bmatrix}
  \xi_{i,n_i} \rho_{i,n_i} (\Lambda_{i,n_i}) \\
  \vdots \\
  \xi_{N,n_n} \rho_{N,n_n} (\Lambda_{N,n_n})
\end{bmatrix}
$$

with $c_{ij} > \delta_{i,n_i,j}$, then we have

$$
\mathcal{L} V_{i,n_i} \leq -c_0 V_{i,n_i} + \sum_{s=1}^{n_i} \beta_s,
$$

where $c_0 = \min_{1 \leq i \leq N, 1 \leq j \leq n_i} 4(c_{ij} - \delta_{i,n_i,j}) > 0$, $\delta_{i,n_i,n_i} = 0$, $\rho_{i,n_i}(\Lambda_{i,n_i}) = c_{i,n_i} + \rho_{i,n_i,1}(\Lambda_{i,n_i})$.

Proof: By (4) one has

$$
\begin{bmatrix}
  u_1 \\
  \vdots \\
  u_N
\end{bmatrix} = - \begin{bmatrix}
  \xi_{i,n_i} \rho_{i,n_i} (\Lambda_{i,n_i}) \\
  \vdots \\
  \xi_{N,n_n} \rho_{N,n_n} (\Lambda_{N,n_n})
\end{bmatrix} + \text{diag} \left( \frac{1}{d_1}, \cdots, \frac{1}{d_N} \right) A \begin{bmatrix}
  u_1 \\
  \vdots \\
  u_N
\end{bmatrix},
$$

which yields

$$
u_i = - \xi_{i,n_i} \rho_{i,n_i} (\Lambda_{i,n_i}) + \frac{1}{d_i} \sum_{s=1}^{n_i} a_{is} u_s.
$$

Substituting (6) into (3) gives (5).

**Remark 2**: The constructive proof in Theorems 1 and 2 proposes a new distributed integrator backstepping design method for nonlinear multi-agent systems for the first time. The traditional integrated backstepping design method used in the single-agent system (Liu et al. 2007; Liu et al. (2008); Li et al. (2011); Li and Wu (2013)) requires that the agent can only use its own information, and does not consider how to deal with the neighbors’ information. Moreover, the design method proposed in Theorems 1 and 2 can deal with the interactions among agents and coupling terms in dynamics effectively.

5. PERFORMANCE ANALYSIS

**Theorem 3**: Under Assumptions 1-3 and the distributed control law (4), the distributed practical output tracking problem for system (1) is solvable.

Proof: Defining $V = \sum_{i=1}^{N} V_{i,n_i}$, by (5) we have

$$
\mathcal{L} V \leq -c_0 V + \beta_0,
$$

where $\beta_0 = \sum_{i=1}^{N} \sum_{s=1}^{n_i} \beta_s$.

By (7) and Theorem 1 in Liu et al. (2007), the closed-loop system (1) and (4) has an almost surely unique solution on $[0, \infty)$.

Let
\[ \chi(t) = (\xi_{11} \cdots \xi_{1,n_1} \cdots \xi_{N_1} \cdots \xi_{N,n_N})^T, \]

\[ \eta_l = \inf\{t : t \geq t_0, |\chi(t)| \geq l\}, \quad \forall l > 0, \]

and \( t_l = \min\{\eta_l - t\} \) for all \( t \geq t_0 \). Since \( |\chi(t)| \) is bounded in the interval \([t_0, t_l]\) a.s., \( V(\chi) \) is bounded on \([t_0, t_l]\) a.s.

From (7), it can be obtained that \( EV \) is also bounded on \([t_0, t_l]\) a.s. Note \( \lim_{l \to \infty} \eta_l = \infty \). Then, letting \( l \to \infty \), by (7) and Dynkin formula in Mao and Yuan (2006) we have

\[ EV(\chi(t)) \leq e^{-c_0(t-t_0)} EV(\chi(t_0)) + \frac{\delta_0}{c_0}(1 - e^{-c_0(t-t_0)}). \]  

(8)

**Step 1.** We firstly show that for any given \( \varepsilon \) and initial value \( x(t_0) \), there is a finite-time \( T(x(t_0), \varepsilon) \) such that

\[ |y(t_0) - y(t)| < \varepsilon, \forall t > T(x(t_0), \varepsilon), \]  

Let \( y = \xi_1 = (\xi_{11} \cdots \xi_{N,1}) \) by (8) one has

\[ |\xi_1| \leq 8(e^{-c_0(t-t_0)}) EV(\chi(t_0)) + \frac{\delta_0}{c_0}(1 - e^{-c_0(t-t_0)}). \]  

(9)

From the definition of \( \xi_1, s = 1, \cdots, N \), it can be seen that

\[ \xi_1 = (L + B)(y - 1)\nu_y. \]  

(10)

By Assumption 3 and (9)-(10) we have

\[ |y - 1\nu_y| \leq 8(L + B)^{-1}\varepsilon^4 e^{-c_0(t-t_0)} EV(\chi(t_0)) + \frac{\delta_0}{c_0}(1 - e^{-c_0(t-t_0)}). \]  

(11)

By (11) and the definition of \( \beta_0 \), for any \( \varepsilon > 0 \) and \( x(t_0) \), one can find a finite-time \( T(x(t_0), \varepsilon) \) and choose \( c_i, \beta_i, i = 1, \cdots, N, j = 1, \cdots, n_i \), such that

\[ |y(t_0) - y(t)| < \varepsilon, \forall t > T(x(t_0), \varepsilon), \quad s = 1, \cdots, N. \]

**Step 2.** We now show that all the states of the closed-loop system are bounded in probability.

Let \( \xi = \chi(t) \) and note that

\[ EV(\xi) \geq \int_{|\xi| > c} V(\xi) P(d\xi) \geq \inf_{|\xi| > c} V(\xi) P(|\xi| > c). \]  

(12)

Then, by (8) and (12) we have

\[ P(|\xi| > c) \leq \frac{EV(\chi(t_0)) + \frac{\delta_0}{c_0}}{\inf_{|\xi| > c} V(\xi)}. \]

By the definition of \( V(\xi) \) one has

\[ \lim_{c \to \infty} \sup_{t_0 < t \leq t_l} \frac{EV(\chi(t_0)) + \frac{\delta_0}{c_0}}{\inf_{|\xi| > c} V(\xi)} = 0. \]  

(13)

By Definition 1 and (13), \( \xi \) is bounded in probability. This together with Assumption 2 and (10) implies \( y_i = x_{i1} \) is bounded in probability, \( i = 1, \cdots, N \).

From the definition of \( \xi_2 \) and (3) we arrive at

\[ \xi_2 = x_{i2} + \xi_{i1} \rho_{i1}(A_{11}) - \frac{\sum \limits_{i=1}^{N} a_{i1} x_{i2}}{di}. \]

which yields

\[ \begin{bmatrix} \xi_{12} \\ \xi_{22} \\ \vdots \\ \xi_{N2} \end{bmatrix} = \begin{bmatrix} \xi_{11} \rho_{11}(A_{11}) \\ \xi_{21} \rho_{21}(A_{21}) \\ \vdots \\ \xi_{N1} \rho_{N1}(A_{N1}) \end{bmatrix} + M \begin{bmatrix} x_{12} \\ x_{22} \\ \vdots \\ x_{N2} \end{bmatrix}. \]  

(14)

Notice that \( \xi_{11}, \xi_2 \) and \( x_{i1} \) are bounded in probability, by Lemma 2 and (14) one can conclude that \( x_{i2} \) is bounded in probability, \( i = 1, \cdots, N \). Similarly, one can prove that \( x_{ij}, i = 1, \cdots, N, j = 3, \cdots, n_i \), are bounded in probability. Therefore, all the states of the closed-loop system are bounded in probability.

Thus, the theorem is true.

**Theorem 4:** Assumption 3 is necessary for the solvability of the distributed practical output tracking problem of the system (1).

**Proof:** If the leader is not the root of any spanning tree in the digraph \( \mathcal{G} \), one can find some followers which are not connected to the leader. For these followers, by choosing different initial values from the leader, the tracking error is not guaranteed to be bounded.

**Remark 3:** From (8) and (11), the outputs of the followers can track the dynamic leader’s output \( y_0(t) \) with an exponential rate. Specifically, the convergence rate depends on the parameter \( c_0 = \min_{1 \leq i \leq N, 1 \leq j \leq n_i} (4(c_{ij} - \delta_{i,n,j})). \)

One can choose larger \( c_{ij} \) to get a faster convergence rate, at a cost of larger control effort.

**Remark 4:** For any \( \varepsilon > 0 \) and \( \varepsilon_0 > 0 \), by (11) and Chebyshev’s inequality in Mao and Yuan (2006), there exists \( T > 0 \) such that for all \( t > T \),

\[ P(|y - 1\nu_y| > \varepsilon) \leq \frac{E[y - 1\nu_y]^4}{\varepsilon^4} \leq \frac{\eta_0}{\varepsilon_0} (L + B)^{-1}\varepsilon^4 + \varepsilon_0 \leq \varepsilon', \]

where \( \varepsilon' \) can be made small enough by choosing parameters appropriately. Therefore, the asymptotic tracking in probability can be achieved in some sense.

**Remark 5:** Let \( d(t) \) be an unknown continuous disturbance or parameter belonging to a known compact set \( \Omega \subset R^3 \). Consider the following more general multi-agent systems with high-order stochastic nonlinear dynamics of the form:

\[ dx_{ij} = (x_{i,j+1} + \tilde{f}_{ij}(x_{ij}, d(t)))dt + \bar{g}_{ij} (x_{ij}, d(t))d\omega, \]

\[ j = 1, \cdots, n_i - 1, \]

\[ dx_{i,n_i} = (u_i + \tilde{f}_{i,n_i}(x_{i,n_i}, d(t)))dt + \bar{g}_{i,n_i}(x_{i,n_i}, d(t))d\omega, \]

\[ y_i = x_{i1}, \]

(15)

where \( f_{ij} \) and \( g_{ij} \) are unknown smooth functions bounded by known nonnegative smooth functions (a same condition presented by Assumption 1), \( i = 1, \cdots, N, j = 1, \cdots, n_i \). If Assumptions 2-3 hold, then by repeating the controller
design and performance analysis process above, the solvability of the distributed practical output tracking problem for system (15) can be shown similarly. Thus, from this point, the results in this paper have some robustness.

6. A SIMULATION EXAMPLE

Consider the following stochastic nonlinear multi-agent systems with $i = 3$:

$$\begin{align*}
    dx_{1i} &= (x_{12} + f_{1i}(x_{1i}))dt + g_{1i}(x_{1i})d\omega, \\
    dx_{2i} &= (u_{i} + f_{2i}(x_{2i}))dt + g_{2i}(x_{2i})d\omega,
\end{align*}$$

$$y_{i} = x_{1i},$$

(16)

where $f_{1i}(x_{1i}) = \frac{1}{3}x_{1i}\sin x_{11}, g_{1i}(x_{1i}) = \frac{1}{3}x_{1i}, f_{12}(x_{12}) = 0, g_{12}(x_{12}) = x_{1i}\sin x_{2}, f_{ij}(x_{ij}) = 0, g_{2j}(x_{2j}) = 0, i = 2, 3, j = 1, 2, g_{31}(x_{31}) = 0, g_{31}(x_{32}) = x_{31}\cos^{2}x_{32}.$

The topology $\mathcal{G}$ is described by $a_{23} = b_{1} = b_{2} = 1, a_{12} = a_{13} = a_{21} = a_{23} = a_{31} = a_{32} = \frac{1}{2}$. The leader’s output $y_{0}(t) = \frac{1}{2}\sin t$.

By choosing $c_{11} = \frac{3}{4}, c_{12} = 1, c_{21} = \frac{3}{5}, c_{22} = 1, c_{31} = 1, c_{32} = \frac{1}{4}$ in the distributed integrator backstepping design procedure developed in Section 4, one can get

$$\begin{align*}
    u_{1} &= -30(2x_{11} + x_{12} - \sin t), \\
    u_{2} &= -56(x_{12} + x_{22} - \frac{1}{4}\sin t), \\
    u_{3} &= -9x_{31} + 3(x_{32} + 5x_{22} + 28x_{21} - 14\sin t)^{2} + 1 + 4x_{31} + x_{32} - x_{21} - x_{22}).
\end{align*}$$

(17)

Letting $c_{i} = y_{i} - y_{0}, i = 1, 2, 3,$ and randomly, setting the initial values $x_{11}(0) = 3, x_{12}(0) = -3, x_{21}(0) = 0.1, x_{22}(0) = 0.4, x_{31}(0) = -3, x_{32}(0) = 0.2$, we obtain Fig. 1, which depicts the response of the closed-loop system and shows the efficiency of the distributed tracking controller.

7. CONCLUDING REMARKS

The distributed tracking problem for multi-agent systems with high-order stochastic nonlinear dynamics is investigated. A distributed integrator backstepping design technique is developed, by which distributed tracking controllers are designed to guarantee that all the states are bounded in probability, and the tracking errors can be tuned to arbitrarily small with a tunable exponential converge rate.

For the distributed control of stochastic nonlinear multi-agent systems, many important issues are still open and worth investigating, such as the distributed controls in the case where communication channel is with unknown parameters, quantization error, etc.
