NTNU, Spring 2014

## CASE-STUDY IN COX-REGRESSION: PBC-DATA FROM MAYO CLINIC

424 patients with PBC (primary biliary cirrhosis (rare disease))
A randomized clinical trial with drug DPCA versus Placebo: 312 patients chosen

Patients included in trial: January 1974 - May 1984
Follow-up until July 1986
First: Compared DPCA group and Placebo group by Kaplan Meier.

Figure 4.4.1 Estimated survival curves in DPCA and placebo groups, PBC data.

Use the same model as for the Battery Data:
$\mathrm{x}=0$ for DCPA $\quad \lambda_{0}(t)$
$\mathrm{x}=1$ for Placebo $\lambda_{0}(t) e^{\beta}$
$\hat{\beta}=-0.0571, W=2(I(\hat{\beta})-I(0))=0.102$ (not significant)
$S D(\hat{\beta})=\frac{1}{-\sqrt{I^{\prime \prime}(\hat{\beta})}}=0.1792$
$95 \%$ confidence interval for $\beta: \hat{\beta} \pm 1.96 \cdot 0.1792$
(-0.408, 0.294)
so Cl for relative risk $e^{\beta}:(0.66,1.34)$
Conclusion: In the best case the new drug leads to 1.34 relative risk for not using it (would need at least 1.50 to do further investigations).

The data on the 312 PBC randomized patients can be used to build a statistical model for the influence of covariates on disease outcome.

The data contains 14 clinical, biochemical and histological variables.
Their model is (now $\lambda(\cdot)$ is used instead of $z(\cdot)$ for hazard rate):

$$
\lambda(t ; \mathbf{x})=\lambda_{0}(t) e^{\beta_{1} X_{1}+\beta_{2} X_{2}+\cdots+\beta_{k} x_{k}}
$$

In the beginning $\mathrm{k}=14$

## COVARIATES

Table 4.4.1 Prognostic Factors: Summary of Univariate Statistics (312 Patients in the PBC Clinical Trial of DPCA)

| Demographic | min | 1st Q | med | 3rd Q | max | Missing | Rao $\chi^{2}$ (1 d.f.) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Age (years) | 26.3 | 42.1 | 49.8 | 56.7 | 78.4 | 0 | 20.86 |
| Sex | male: | 36 | female: | 276 |  | 0 | 4.27 |
| Clinical |  | Absent |  | Present |  | Missing | Rao $\chi^{2}$ (1 d.f.) |
| Ascites |  | 288 |  | 24 |  | 0 | 104.02 |
| Hepatomegaly |  | 152 |  | 160 |  | 0 | 40.18 |
| Spiders |  | 222 |  | 90 |  | 0 | 30.31 |
| Edema ${ }^{1}$ | 0: 263 | 1/2: | 29 | 1: 20 |  | 0 | 97.89 |
| Biochemical | min | 1st Q | med | 3rd Q | max | Missing | Rao $\chi^{2}$ (1 d.f.) |
| Bilirubin | 0.3 | 0.8 | 1.35 | 3.45 | 28.0 | 0 | 190.62 |
| Albumin | 1.96 | 3.31 | 3.55 | 3.80 | 4.64 | 0 | 70.83 |
| Urine Copper | 4 | 41 | 73 | 123 | 588 | 2 | 84.35 |
| Pro Time | 9.0 | 10.0 | 10.6 | 11.1 | 17.1 | 0 | 51.76 |

| SGOT | 26 | 81 | 115 | 152 | 457 | 0 | 29.59 |
| Histologic | 1 | 2 | 3 | 4 |  | Missing | Rao $\chi^{2}$ (1 d.f.) |
| Stage | 16 | 67 | 120 | 109 |  | 0 | 46.49 |

$\rightarrow$ Bilirubin most significant
$\rightarrow$ Take out expensive/complicated covariates:
stage, urine, copper, SGOT
Remains 11 variables; then a step-down procedure is used to eliminate one (non-significant) variable at a time, arriving at lower table on next slide.

## VARIABLE SELECTION: TABLE

Table 4.4.2 Results of variable selection procedure in 312 randomized cases with PBC.

| (a) First Step, log likelihood -550.603 |  |  |  |
| :---: | :---: | :---: | :---: |
|  | Coef. | Std. Err. | Z stat. |
| Age | 2.819 e-2 | 9.538 e-3 | 2.96 |
| Albumin | -9.713 e-1 | $2.681 \mathrm{e}-1$ | -3.62 |
| Alk. Phos | 1.445 e-5 | 3.544 e-5 | 0.41 |
| Ascites | 2.813 e-1 | $3.093 \mathrm{e-1}$ | 0.91 |
| Bilirubin | 1.057 e-1 | $1.667 \mathrm{e}-2$ | 6.34 |
| Edema | 6.915 e-1 | 3.226 e-1 | 2.14 |
| Hepatomegaly | 4.853 e-1 | 2.913 e-1 | 2.21 |
| Platelets | -6.063 e-4 | $1.025 \mathrm{e}-3$ | -0.59 |
| Prothrombin Time | 2.428 e-1 | 8.420 e-2 | 2.88 |
| Sex | -4.769 e-1 | $2.643 \mathrm{e}-1$ | -1.80 |
| Spiders | 2.889 e-1 | 2.093 e-1 | 1.38 |

(b) Last Step, log likelihood -554.237

|  | Coef. |  | Std. Err. |  |
| :--- | ---: | ---: | ---: | ---: |
|  |  |  | Z stat. |  |
|  | 0.0338 |  | 0.00925 |  |
| Age | -1.0752 | 0.24103 | -4.46 |  |
| Albumin | 0.1070 | 0.01528 | 7.00 |  |
| Bilirubin | 0.8072 | 0.30775 | 2.62 |  |
| Edema | 0.5903 | 0.21179 | 2.79 |  |
| Hepatomegaly | 0.2603 | 0.07786 | 3.34 |  |

Table 4.4.2: Cox with 11 variable.
Recall: Z stat means Coef/Std.Err.
Step-down procedure: From (a) to (b): 5 variables taken out;
Log-likelihood statistic:
2. difference in log likelihood $=7.268$
should be compared to $\chi_{5}^{2}: P\left(\chi_{5}^{2}>7.268\right)=0.201$, so we do not reject the null hypothesis that all these 5 variables have coefficients equal to 0 .

Then is considered log-transformations of continuous variables - four variables using logs are added to model, and this leads to increased likelihood!

Finally: Arrives at model 4.4.3(c)

Table 4.4.3 Regression models with log transformations of continuous variables, 312 randomized cases with PBC.

|  | (a) Log likelihood -538.274 |  | Z stat. |

(b) Log likelihood -541.064

|  | Coef. | Std. Err. | Z stat. |
| :---: | :---: | :---: | :---: |
| Age | 0.0337 | 0.00864 | 3.89 |
| Albumin | -0.9473 | 0.23713 | -3.99 |
| $\log$ (Bilirubin) | 0.8845 | 0.09854 | 8.98 |
| Edema | 0.8006 | 0.29914 | 2.68 |
| Prothrombin Time | 0.2463 | 0.08426 | 2.92 |

(c) Log likelihood -540.412

|  | Coef. | Std. Err. | Z stat. |
| :---: | :---: | :---: | :---: |
| Age | 0.0333 | 0.00866 | 3.84 |
| $\log$ (Albumin) | -3.0553 | 0.72408 | -4.22 |
| $\log$ (Bilirubin) | 0.8792 | 0.09873 | 8.90 |
| Edema | 0.7847 | 0.29913 | 2.62 |
| $\log$ (Prothrombin Time) | 3.0157 | 1.02380 | 2.95 |

Recall:

$$
S(t ; \mathbf{x})=P(T>t ; \mathbf{x})=S_{0}(t)^{e^{\boldsymbol{\beta}^{\prime}}{ }_{\mathbf{x}}}=e^{-\Lambda_{0}(t) e^{R}}
$$

where $R=\beta_{1} x_{1}+\beta_{2} x_{2}+\cdots+\beta_{k} x_{k}=\boldsymbol{\beta}^{\prime} \mathbf{x}$ is called Risk Score.
Estimated value: $\hat{S}(t ; \mathbf{x})=e^{-\hat{\Lambda}_{0}(t) e^{\hat{R}}}$
In the data we have the median value: $\hat{R}=5.24$, and for this value we get the one- and five-year survival estimates:
$\hat{S}(1)=0.982$
$\hat{S}(2)=0.845$
A low-risk example:
Bilirubin 0.5; Albumin 4.5; Age 52; Prothrombin 10.1; edema 0; gives

$$
\hat{R}=0.879 \cdot \ln 0.5-3.0553 \cdot \ln 4.5-\cdots=3.49
$$

so $\Rightarrow \hat{S}(5)=0.97$

Suppose we want to find the distribution ( $R(t)$, MTTF, etc.) for the lifetime of a product.

Problem: MTTF may be so large that one would need to let experiments last several years.

Solution: Increase stress, use a regression model, and then extrapolate to normal conditions.

## ACCELERATED LIFE TESTING: INSULATION DATA

Suppose you want to investigate the deterioration of an insulation used for electric motors. The motors normally run between 80 and 100 degrees Celsius.

To save time and money, you decide to use accelerated life testing.
First you gather failure times for the insulation at abnormally high temperatures: 110, 130, 150, and 170 degrees Celsius, to speed up the deterioration. With failure time information at these temperatures, you can then extrapolate to 80 and 100 degrees.

It is known that an Arrhenius relationship exists between temperature and failure time.

This is an example from MINITAB (next slide)

## Equation

Lifetime regression

The regression model estimates the percentiles of the failure time distribution:
$Y=\beta 0+61 X+\sigma \varepsilon$
where:
$Y=$ either failure time or bo(failure time)
Ab - y-intercept (constont)
$\beta_{1}=$ regression coefficent
X = predictor values (may be trans formed)
$\sigma=1 /$ shape (Weibul dstribution) or scae (other distributions)
$\varepsilon=$ random error term

## Response

## variable

Depending on the distribution, $\mathrm{Y}=$ failure time or $\log$ (failure fime)

- For the V/ebull, exponential, lognormal, and ioglogistic distributions, $Y=\log$ (failure time)
- For the normal, extreme value, and logistic distributions, $\mathrm{Y}=$ failure time When $Y=\log$ (failure time), Mintab takes the antilog to display the percentiles on the original scale.

Error term The value of the error distribution also depends on the distribution chosen.

- For the normal distribution the error distribution is the standard normal distribution - normal ( 0,1 ) For the lognormal detribution, Minitab takee the $\log$ baeee of the data and ueee a normal distribution.
* For the logistic distribution, the error distrbution is the stendard logistic distribution - logistc ( 0 , 1). For the loglogstic distrbution, Mintab takes the log of the data and uses a logstic distrbution.
- For the extreme value distribution, the error distribution is the standard extreme value distribution - extreme value $(0,1)$. For the Weioull distribution and the exponential distribution (a type of

| 50 | 100.0000 | 36948.57 | 4216.511 | 29543.36 | 46209.94 |

In this example we need connection between lifetime $(T)$ and temperature.
Some standard relations are known to be useful in accelerated testing:

$$
\ln T=\beta_{0}+\beta_{1}(\text { function of accelerated variable })+\sigma W
$$

i.e. $\ln T=\beta_{0}+\beta_{1} g(s)$ for some function $g(\cdot)$ of the stress.

The model used here is the Arrhenius model:

$$
\ln T=\beta_{0}+\beta_{1} \cdot \frac{11604.83}{s+273.16}+\frac{1}{\alpha} W
$$

where $W$ is Gumbel and $s=$ temperature in ${ }^{\circ} \mathrm{C}$, so $s+273.16=$ temp in ${ }^{\circ} \mathrm{K}$ (absolute temperature).

This is the same as computing a transformed covariate.
$x=\frac{11604.83}{s+273.16}$.
Estimated model:

$$
\ln T_{s}=-15.874+0.83072 \cdot \frac{11604.83}{s+273.16}+\frac{1}{2.8246} W
$$

## Probability Plot (Fitted Arrhenius) for FailureT

Weibull Distribution - ML Estimates - 95,0\% CI
Censoring Column in Censor

Normal temperature is $80-100 \mathrm{C}$.
Experiment temperatures: 110, 130, 150, 170. Needs to extrapolate to 80-100, using Arrhenuis model.

Recall probability plot for Weibull:
$\ln (-\ln R(t))=\alpha \ln T-\alpha \ln \theta$
So:

- Slope $\alpha$ is the same for all lines
- Scale $\theta=\beta_{0}+\beta_{1} \cdot \frac{11604.83}{s+273.16}$ depends on experiment temperature $s$.

## Relation Plot (Fitted Arrhenius) for FailureT

Weibull Distribution - ML Estimates - 95,0\% CI
Censoring Column in Censor

Plot $\hat{t}_{p}(s)$ as function of $s$.
Recall general formula:

$$
\ln \hat{t}_{p}(\mathbf{x})=\beta_{0}+\boldsymbol{\beta}^{\prime} \mathbf{x}+\sigma \Phi^{-1}(p)
$$

where for Weibull/Gumbel we have $\Phi^{-1}(p)=\ln (-\ln (1-p))$. Here:

$$
\ln \hat{t}_{p}(s)=-15.1874+0.83072 \cdot \frac{11.60483}{s+273.16}+\frac{1}{2.8246} \cdot \ln (-\ln (1-p))
$$

Figure shows median, $p=0.50$, together with $95 \%$ confidence curves; and in addition the curves for $p=0.10$ and $p=0.90$.
