

FINDING A CLUSTER-TILTING OBJECT FOR A REPRESENTATION FINITE CLUSTER-TILTED ALGEBRA

M. A. BERTANI-ØKLAND (TRONDHEIM), S. OPPERMANN (TRONDHEIM),
AND A. WRÅLSEN (TRONDHEIM)

ABSTRACT. We provide a technique to find a cluster-tilting object having a given cluster-tilted algebra as endomorphism ring in the finite type case.

1. INTRODUCTION

The cluster category of a finite dimensional hereditary algebra H over an algebraically closed field k was first introduced in [6]. It provides a categorical model for the cluster algebras of Fomin and Zelevinsky [10], as well as a generalization of the classical tilting theory (see for instance [1]). The first link from cluster algebras to tilting theory was given in [12] with *decorated representations of quivers*, and later the cluster category was defined as a factor category of the derived category of H .

In the cluster category we have a special class of objects, namely the *cluster-tilting objects*. They induce the *cluster-tilted algebras*, which have been extensively studied (see for instance [3], [4], [5]). The topic of this paper is the relationship between cluster-tilting objects and cluster-tilted algebras in the finite type case. More specifically we will study the distribution of cluster-tilting objects in the Auslander Reiten quiver (AR-quiver for short) of the cluster category and the quivers of cluster-tilted algebras.

Given a cluster-tilting object in a cluster category \mathcal{C} of finite type and its distribution within the AR-quiver of \mathcal{C} , it is easy to read off the quiver with relations of the cluster-tilted algebra induced by it. We present a technique to solve the opposite problem - namely, given the quiver with relations of a cluster-tilted algebra of finite type, how can we find a cluster-tilting object having it as its endomorphism ring? The technique uses a correspondence between subfactor categories of the cluster category and subquivers of Q . Along the way we obtain a new proof of the classification of quivers of cluster tilted algebras of type \mathbb{D}_n (first obtained in [15]).

2. BACKGROUND

2.1. Cluster categories and cluster-tilting objects. Let H be a finite dimensional hereditary algebra H over an algebraically closed field k . We

Date: March 22, 2010.

1991 Mathematics Subject Classification. Primary: 16G20; Secondary: 16G70.

Key words and phrases. Cluster category, cluster-tilting object, cluster-tilted algebra, Auslander-Reiten quiver.

then define its cluster category \mathcal{C} as an orbit category of its bounded derived category $D^b(H)$, namely the category

$$\mathcal{C} = D^b(H)/F,$$

where $F = \tau^{-1}[1]$ is the composition of the automorphism τ^{-1} , the inverse of the AR-translate of $D^b(H)$, with the shift functor $[1]$. The objects of \mathcal{C} are orbits of the objects of $D^b(H)$, while $\text{Hom}_{\mathcal{C}}(A, B) = \bigoplus_i \text{Hom}_{\mathcal{D}}(A, F^i B)$ (see [6] for more details). Since the indecomposable objects of $D^b(H)$ are isomorphic to stalk complexes, we can consider them as shifts of indecomposable objects in $\text{mod } H$, and thus all morphisms in \mathcal{C} are induced by morphisms and extensions in $\text{mod } H$.

A *cluster-tilting object* in \mathcal{C} is an object T such that $\text{Ext}_{\mathcal{C}}^1(T, X) = 0$ if and only if X is in $\text{add } T$ for any object X in \mathcal{C} . The cluster-tilting objects coincide with the *maximal rigid objects*, that is, objects that are rigid (i.e. with no self-extensions) and are maximal with this property ([6]). Throughout this paper we assume that T is basic. These objects can be considered to be generalizations of tilting modules, and all such objects are in fact induced by tilting modules in $\text{mod } H'$ for some hereditary algebra H' derived equivalent to H ([6, 3.3]). In particular they have exactly n nonisomorphic indecomposable summands, where n is the number of nonisomorphic simple modules of H .

In this paper we only consider cluster categories of finite type. This means that H is Morita equivalent to the path algebra kQ where k is an algebraically closed field and Q is a simply laced Dynkin quiver. We then say that \mathcal{C} is of type Δ , where Δ is the Dynkin type of Q . In these cases the combinatorics of the AR-quivers of $\text{mod } H$ is very well-known, and we will rely heavily on this.

2.2. Cluster-tilted algebras of finite type. A *cluster-tilted algebra* is the endomorphism algebra $B = \text{End}_{\mathcal{C}}(T)^{\text{op}}$ of a cluster-tilting object T in \mathcal{C} . By [4] we know that B is of finite representation type if and only if H is of finite representation type. If H is of Dynkin type Δ , we say that B is cluster-tilted of type Δ .

Finite type cluster-tilted algebras are (up to Morita equivalence) determined uniquely by their quiver by [3]. Furthermore, under our assumptions they are of the form kQ/I , where Q is a finite quiver and I some finitely generated admissible ideal in the path algebra kQ (see [1], [2]).

If the elements of I are linear combinations $k_1\rho_1 + \dots + k_n\rho_n$ of paths ρ_i in Q , all starting and ending at the same vertex, such that each k_i is non-zero in k , they are called *relations*. A *zero-relation* is a relation such that $n = 1$. If $n = 2$, we call it a *commutativity-relation*. A relation r is called *minimal* if we have that whenever $r = \sum \alpha_i \rho_i \beta_i$, where ρ_i is a relation for every i , then there exists an index j such that both α_j and β_j are scalars. Furthermore, whenever there is an arrow $b \rightarrow a$, a path from a to b is called *shortest* if it contains no proper subpath which is a cycle and if the full subquiver generated by the induced oriented cycle contains no further arrows. We also say that two paths from j to i are *disjoint* if they have no common vertices except j and i , and we say that two disjoint paths from j to i are *disconnected* if the full subquiver generated by the paths contains no further

arrows except possibly an arrow from i to j . More details on this can be found in [3]. Then the following theorem sums up many properties of I :

Theorem 2.1. [3] *Let Q be a finite quiver, k an algebraically closed field and I an ideal in the path algebra kQ , such that $B = kQ/I$ is a cluster-tilted algebra of finite representation type, and let a and b be vertices of Q .*

- (a) *Assume that there is an arrow $b \rightarrow a$. Then there are at most two shortest paths from a to b .*
 - (i) *If there is exactly one, this is a minimal zero-relation.*
 - (ii) *If there are two, r and s , then r and s are not zero in B , they are disconnected, and there is a minimal commutativity-relation $r + \lambda s$ for some $\lambda \neq 0$ in k .*
- (b) *Up to multiplication by non-zero elements of k , there are no other zero-relations or commutativity-relations.*
- (c) *The ideal I is generated by minimal zero-relations and minimal commutativity-relations.*

2.3. Realizing smaller cluster categories inside bigger ones. Throughout this section we fix a hereditary algebra H and an indecomposable rigid object M in $D^b(H)$.

Several people have noted a class of subfactor categories of the cluster category that are equivalent to smaller cluster categories (smaller here meaning that they are induced by a hereditary algebra with fewer isoclasses of simples). See for instance [5], [9] or [11]. The latter paper treats this for a more general setup, namely 2-CY triangulated categories with a cluster-tilting object. We thus have the following proposition:

Proposition 2.2. *Let \mathcal{C} be the cluster category of a hereditary algebra H , and let $M \in \mathcal{C}$ be indecomposable and rigid. Then*

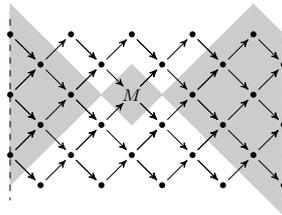

$$M_{\mathcal{C}}^{\perp} = \{X \in \mathcal{C} \mid \text{Hom}_{\mathcal{C}}(X, M[1]) = 0\}/(M),$$

(the category obtained from the subcategory of \mathcal{C} consisting of all objects not having extensions with M by killing maps factoring through M) is equivalent to the cluster category \mathcal{C}' of a hereditary algebra H' with exactly one fewer isoclasses of simple objects than H .

If M is a shift of an indecomposable projective module He , then $M_{\mathcal{C}}^{\perp}$ is the cluster category of H/HeH .

This concrete realization of \mathcal{C}' in \mathcal{C} is fundamental for this paper. We give an example below:

Example 2.3. Let H be of Dynkin type \mathbb{A}_6 , and let M be the object of \mathcal{C} indicated in the following drawing of the AR-quiver of \mathcal{C} (the dashed lines indicate which objects are identified under F):

The objects that are shaded here are the objects *not* in $M_{\mathcal{C}}^{\perp}$. It is not hard to see that the remaining objects (modulo all maps factoring through M) form a cluster category of type $A_2 \amalg A_3$.

We then have the following useful corollary:

Corollary 2.4 ([11, 4.9]). *Let M be a rigid indecomposable object in the cluster category \mathcal{C} of H . Then there is a bijection between cluster-tilting objects in \mathcal{C} containing M and cluster-tilting objects in \mathcal{C}' .*

In particular this means that given a cluster-tilting object T and removing any summand T' will give an object T/T' that is again a cluster-tilting object in a cluster category (though now possibly disconnected) that is equivalent to a subfactor category of the original cluster category.

3. SUBFACTOR CATEGORIES OF DYNKIN TYPE \mathbb{A}_n

In this section we focus on the quivers of cluster-tilted algebras of type \mathbb{A}_n and how these always can be assumed to be induced by cluster-tilting objects living in a domain of the cluster category corresponding to $\text{mod } kQ_m$ where Q_m is \mathbb{A}_m with linear orientation. We also show that the same happens for certain subquivers of quivers of cluster-tilted algebras of type \mathbb{D}_n .

3.1. Quivers of type \mathbb{A} and triangles in cluster categories. By [7] the class of quivers of cluster-tilted algebras of type \mathbb{A}_n can be described as follows (equivalent classifications can be found in [14] and implicitly in [8]).

- (a) all non-trivial cycles are oriented and of length 3
- (b) a vertex has at most four neighbours
- (c) if a vertex has four neighbours, then two of its adjacent arrows belong to one 3-cycle, and the other two belong to another 3-cycle
- (d) if a vertex has exactly three neighbours, then two of its adjacent arrows belong to a 3-cycle, and the third arrow does not belong to any 3-cycle

In particular there are no non-oriented cycles in such a quiver (and thus no multiple arrows). Actually such a quiver is always a full connected subquiver of the infinite quiver \mathcal{Q} drawn below:

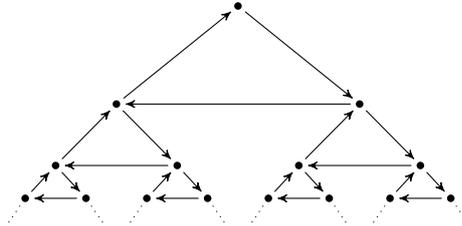

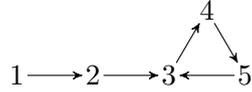

Figure 3.1

where the composition of any two arrows on a 3-cycle is zero. In such a quiver we will call a vertex a *connecting vertex* (this notation has been introduced in [15]) if

- (a) there are at most two arrows adjacent with it, and

- (b) whenever there are two arrows adjacent with it, the vertex is on a 3-cycle.

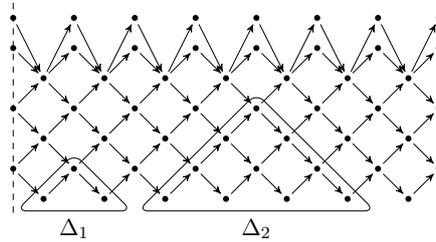

For instance, in the quiver

the vertices 1, 4 and 5 are connecting vertices, while the vertices 2 and 3 are not.

Next we define what we mean by an \mathbb{A} -triangle in a quiver. It is simply the quiver of a cluster-tilted algebra of Dynkin type \mathbb{A}_m with exactly one connecting vertex marked. It is easy to see that the quiver of any cluster-tilted algebra of type \mathbb{A} has at least one connecting vertex, so we just have to choose one. In particular we can always assume that the marked connecting vertex corresponds to the top vertex in the picture of \mathcal{Q} in Figure 3.1.

Now we move on to a class of subcategories of cluster categories that we will refer to as *triangles of order m in \mathcal{C}* . As already indicated they correspond to domains in the AR-quiver of \mathcal{C} corresponding to $\text{mod } kQ_m$. Thus any rigid object in such a triangle is induced by a partial tilting module over kQ_m , and if the object is maximal within the triangle it corresponds to a tilting module. Below are two examples of triangles of order 2 and 4 in a cluster category of type \mathbb{D}_7 :

We also denote the object in a triangle Δ that corresponds to the projective-injective module over kQ_m by $\Pi(\Delta)$. Since every maximal rigid object in Δ corresponds to a tilting module over kQ_m , it always has $\Pi(\Delta)$ as a summand.

Next we will show that any cluster-tilting object of type \mathbb{A}_m is induced by a tilting module over $\text{mod } kQ_m$.

Lemma 3.1. *Every cluster-tilting object T in the cluster category \mathcal{C}_m of type \mathbb{A}_m has at least two summands in the outmost τ -orbit in the AR-quiver of \mathcal{C}_m .*

Proof. Clearly this is the case for \mathcal{C}_2 .

Now assume that the claim holds for any $m' < m$. Since m can be assumed to be at least 3, either the result holds or T must have at least one indecomposable summand T_* that is not in the outer τ -orbit of the AR-quiver. We then know that T_*^\perp looks as follows in \mathcal{C}_m :

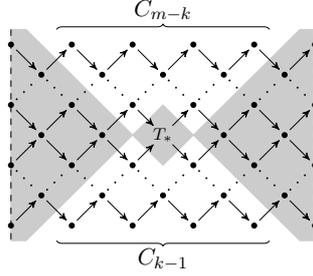

Figure 3.2

T_*^\perp is equivalent to $\mathcal{C}_{k-1} \times \mathcal{C}_{m-k}$, and we can, by Corollary 2.4, write $T = T_* \oplus T_1 \oplus T_2$ where T_1 is a cluster-tilting object in \mathcal{C}_{k-1} and T_2 is a cluster-tilting object in \mathcal{C}_{m-k} .

The domain of \mathcal{C}_{k-1} in \mathcal{C}_m is defined by the objects below T_* in the above figure. By assumption every cluster-tilting object in \mathcal{C}_{k-1} must have at least two summands in the top τ -orbit of its AR-quiver. We note that this cannot be the two objects directly below T_* since there is a non-zero extension between them. Thus T_1 must have at least one summand in the bottom row of the AR-quiver of \mathcal{C}_{k-1} and thus of \mathcal{C}_m . A similar argument holds for T_2 and \mathcal{C}_{m-k} , and so we are done. \square

Lemma 3.2. *Every cluster-tilting object T in the cluster category \mathcal{C}_m is induced by a tilting module over kQ_m , where Q_m is of type \mathbb{A}_m with linear orientation.*

Proof. This result follows from the very simple observation that the objects that have non-zero extensions with an object in the outmost row of the AR-quiver can be seen as $kQ_m[1]$ for some embedding of kQ_m into \mathcal{C}_m . Since none of these objects can be summands of T , the result follows. \square

The next proposition tells us which summands of a cluster-tilting object T can induce connecting vertices in the quiver of $\text{End}(T)^{\text{op}}$:

Proposition 3.3. *Let T be a cluster-tilting object in the cluster category \mathcal{C}_m of type \mathbb{A}_m . Then an indecomposable summand T_* of T induces a connecting vertex in the quiver Q of $\text{End}(T)^{\text{op}}$ if and only if it is in the outmost τ -orbit in the AR-quiver of \mathcal{C}_m .*

Proof. First, from the AR-quiver of \mathcal{C}_m it is easy to check that an object in the outmost τ -orbit in the AR-quiver will induce a connecting vertex in Q .

Next, assume that an indecomposable summand T_* of T that is not in the outmost row of the AR-quiver of \mathcal{C}_m induces a connecting vertex. Consider Figure 3.2. Since T_* is not on the outmost row, T_*^\perp decomposes into two non-connected subcategories containing $k-1$ and $n-k$ summands of T respectively.

If there is only one other indecomposable summand of T with an irreducible map to or from T_* , this would mean that Q is a disconnected quiver since there must be at least one summand of T in each subcategory. Thus this cannot happen.

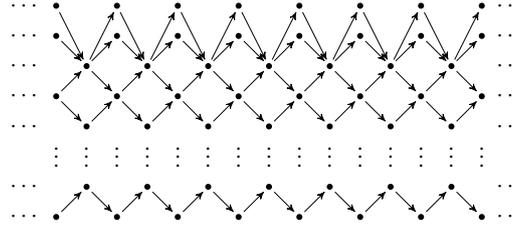

Hence assume that T_* corresponds to a vertex on a 3-cycle. In this case the other summands in the cycle would have to be either both in \mathcal{C}_{k-1} or both in \mathcal{C}_{m-k} , since there is no non-zero map completing the triangle otherwise. Again this would disconnect the quiver, and so it cannot happen. \square

The following corollary is a consequence of the results of this section.

Corollary 3.4. *Let $m \leq n - 2$. Then every \mathbb{A} -triangle with m vertices and every maximal rigid object in a triangle of order m in the cluster category \mathcal{C} of type \mathbb{D}_n is induced by a tilting module over $\text{mod } kQ_m$ where Q_m is of type \mathbb{A}_m with linear orientation. Thus every \mathbb{A} -triangle with m vertices corresponds to some maximal rigid object in a triangle in \mathcal{C} of order m , and every maximal rigid object in a triangle of order m in \mathcal{C} induces an \mathbb{A} -triangle with m vertices.*

3.2. Subcategories of Dynkin type \mathbb{A} in the cluster category of type \mathbb{D} . In this subsection we develop some lemmas which will be used to show the main results of this paper. Throughout this subsection we will assume that \mathcal{C} is a cluster category of Dynkin type \mathbb{D}_n .

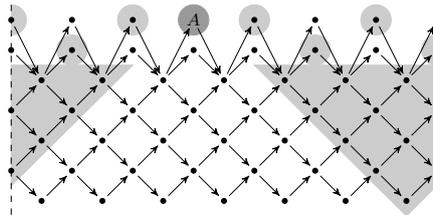

From now on let $H = kQ$, where Q is some orientation of \mathbb{D}_n . Then the AR-quiver of $D^b(H)$ is of the form $\mathbb{Z}Q$ and can be drawn as follows:

When the AR-quiver of \mathcal{C} is drawn as above, we will refer to the objects in the top two rows of the AR-quiver of $D^b(H)$ as α -objects and to the remaining objects as β -objects.

Definition 3.5. Let A be an α -object. Then ϕA is the unique other α -object which occurs together with A as a summand of the middle term of an almost split triangle.

This means that ϕA is the α -object drawn directly below or above A in the AR-quiver above. The Ext-supports of the objects in this category are well-known. Assuming that A is an α -object in \mathcal{C} , we illustrate $A_{\mathcal{C}}^{\perp}$ in the AR-quiver of \mathcal{C} as follows.

Here the dashed lines indicate which objects are identified by the functor F .

Assume that T is a cluster-tilting object having A as a summand. By Corollary 2.4 we have the following lemma:

Lemma 3.6. *Let T be a cluster-tilting object in \mathcal{C} , and assume that A is a summand in T . Then $T = T_1 \oplus T_2$ where T_1 is the sum of all indecomposable α -objects in T and T_2 is the sum of all β -objects. If T' is the image of T in $A_{\mathcal{C}}^{\perp}$, then $T' = T'_1 \oplus T'_2$ such that T'_1 is isomorphic to T_1/A and T'_2 is isomorphic to T_2 .*

The category $\mathcal{C}' = A_{\mathcal{C}}^{\perp}$ is a cluster category of Dynkin type \mathbb{A} by Theorem 2.2. We set $\mathcal{B}(A) = (\phi A)_{\mathcal{C}'}^{\perp}$. This category is the cluster category of some product of path algebras of Dynkin type \mathbb{A} . In particular it must be the intersection of $A_{\mathcal{C}}^{\perp}$ and $(\phi A)_{\mathcal{C}'}^{\perp}$, and thus it consists of all β -objects in $A_{\mathcal{C}}^{\perp}$. From the above figure we see that this is the domain of the cluster category of Dynkin type A_{n-2} .

As demonstrated in the previous section, there are many triangles in \mathcal{C} . We now define two particular triangles $\mathcal{B}_*(A)$ and $*\mathcal{B}(A)$ and the subcategory $\mathcal{B}(A)$.

Definition 3.7. Let \mathcal{C} , A and $A_{\mathcal{C}}^{\perp}$ be as above. Then we define $\mathcal{B}_*(A)$ to be the subcategory $\{B \in \mathcal{B}(A) \mid \text{Hom}_{\mathcal{C}}(B, A) = 0\}$ and $*\mathcal{B}(A)$ to be the subcategory $\{B \in \mathcal{B}(A) \mid \text{Hom}_{\mathcal{C}}(A, B) = 0\}$ in \mathcal{C} . We also define $\mathcal{B}(A) = \mathcal{B}_*(A) \cup * \mathcal{B}(A)$.

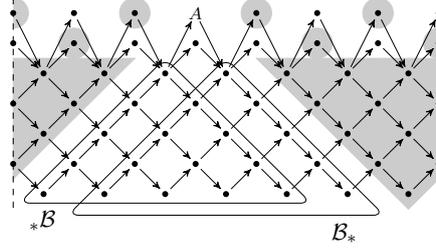

Figure 3.3

We then have the following lemma which is easily seen to be true by Figure 3.3.

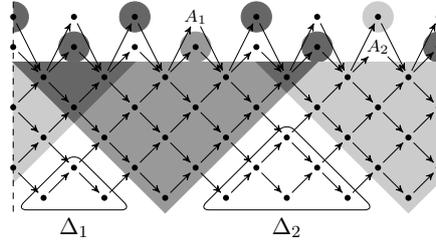

Lemma 3.8. *If Δ is a triangle in $\mathcal{B}(A)$, then any map from A to an object in Δ and any map from an object in Δ to A must factor through $\Pi(\Delta)$.*

Next we give a lemma that explains some of the relationship between $\mathcal{B}(A_1)$ and $\mathcal{B}(A_2)$ for two α -objects A_1 and A_2 in \mathcal{C} .

Lemma 3.9. *Let A_1 and A_2 be two α -objects such that $A_1 = \tau^k A_2$ or $\tau^k(\phi A_2)$ for some k , $0 < k < n$. Then $\mathcal{B}(A_1) \cap \mathcal{B}(A_2)$ is the union of two disjoint triangles Δ_1 and Δ_2 of order $k-1$ and $n-k-1$, respectively, such that*

- (a) every map from A_1 to A_2 factors through $\Pi(\Delta_2)$,
- (b) every map $f : X_1 \rightarrow X_2$ where $X_1 \in \Delta_1$ and $X_2 \in \Delta_2$ factors through A_1 ,
- (c) there is a non-zero map $f : \Pi(\Delta_2) \rightarrow \Pi(\Delta_1)$ which factors through A_2 , and
- (d) $\text{Hom}_{\mathcal{C}}(X, A_1) = 0$ for $X \in \Delta_2$ and $\text{Hom}_{\mathcal{C}_H}(A_1, Y) = 0$ for any $Y \in \Delta_1$.

Proof. By considering $\mathcal{B}(A) \cap \mathcal{B}(\tau^k A)$ for $0 < k < n$ we see that $\mathcal{B}(A_1) \cap \mathcal{B}(A_2)$ is the union of two disjoint triangles of order $k-1$ and $n-k-1$. The following diagram illustrates this:

It is also clear from this that every map from A_1 to A_2 factors through $\Pi(\Delta_2)$. Furthermore, if there was a non-zero map f from some object in Δ_2 to A_1 , it would have to factor through $\Pi(\Delta_2)$ by Lemma 3.8. Since $\text{Hom}_{\mathcal{C}}(A_1, \Pi(\Delta_2))$ is non-zero, these maps would induce a 2-cycle in the quiver of any cluster-tilted algebra induced by a cluster-tilting object having A_1 and $\Pi(\Delta_2)$ as summands. This is a contradiction to a result of Todorov (see [5, Proposition 3.2]).

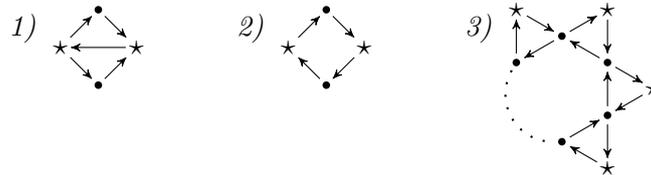

Next we argue that every map $f : X_1 \rightarrow X_2$ where $X_1 \in \Delta_1$ and $X_2 \in \Delta_2$ factors through A_1 . Since $\mathcal{B}(A_1)$ corresponds to the cluster category \mathcal{C}'' of Dynkin type \mathbb{A}_{n-2} , it is clear from the figure that $\text{Hom}_{\mathcal{C}''}(X_1, X_2) = 0$ for $X_1 \in \Delta_1, X_2 \in \Delta_2$. Thus any non-zero map in $\text{Hom}_{\mathcal{C}}(X_1, X_2)$ must factor through A_1 .

Since there is no non-zero map from an object in Δ_1 to an object in Δ_2 in $\mathcal{B}(A_1)$, there must be a non-zero map $f : X'_2 \rightarrow X'_1$ where $X'_2 \in \Delta_2$ and $X'_1 \in \Delta_1$ (otherwise A_1^\perp would be disconnected). But by the previous paragraph this map factors through A_2 , and by Lemma 3.8 it must also factor through $\Pi(\Delta_2)$ and $\Pi(\Delta_1)$. \square

4. THE DISTRIBUTION OF CLUSTER-TILTING OBJECTS OF TYPE \mathbb{D}_n

In this section we will show how to, given the quiver Q of a cluster-tilted algebra of type \mathbb{D}_n , explicitly find a cluster-tilting object in the cluster category of type \mathbb{D}_n inducing it. The goal is to prove the following theorem:

Theorem 4.1. *A quiver Q of a cluster-tilted algebra of type \mathbb{D} is of one of the types*

where the \star -vertices are connecting vertices of possibly empty \mathbb{A} -triangles and all relations are according to Theorem 2.1. In particular we have the following:

- (a) If Q is of type 1), it is induced by a cluster-tilting object having exactly two α -objects A and ϕA as summands.

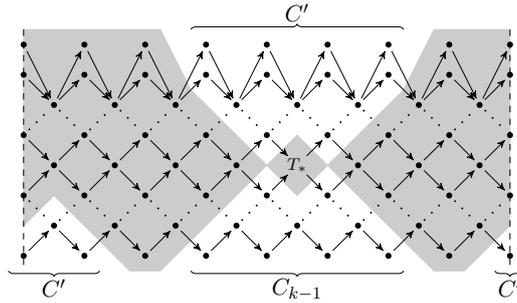

- (b) If Q is of type 2), it is induced by a cluster-tilting object having exactly two α -objects A_1 and A_2 such that $A_2 \neq \phi A_1$ as summands. Furthermore, if the number of vertices in the two \mathbb{A} -triangles are n_1 and n_2 , then we can choose A_1 and A_2 such that A_1 is in $\{\tau^{n_1+1}A_2, \tau^{n_1+1}\phi A_2\}$ and A_2 is in $\{\tau^{n_2+1}A_1, \tau^{n_2+1}\phi A_1\}$.
- (c) If Q is of type 3) it is induced by a cluster-tilting object having more than two α -objects as summands. Furthermore the α -objects are distributed within the AR-quiver of \mathcal{C} according to the number of vertices in the \mathbb{A} -triangles as in b).

Remark. Note that this is enough to find the distribution of some tilting object T inducing the quiver of a given cluster-tilted algebra, since the number and distribution of the α -objects determines the shape of the quiver up to \mathbb{A} -triangles as indicated in the theorem.

What we do is to give the correspondence between triangles of order m in \mathcal{C} and the \mathbb{A} -triangles appearing in the quiver Q . We will argue that every \mathbb{A} -triangle attached to a \star -vertex of the quivers of Theorem 4.1 is induced by a rigid object in a triangle in the cluster category of type \mathbb{D}_n which is maximal within the triangle, and that any such object induces an \mathbb{A} -triangle. First we show that any cluster-tilting object has summands that are α -objects:

Lemma 4.2. *Any cluster-tilting object in the cluster category \mathcal{C} of type \mathbb{D}_n has at least two non-isomorphic α -objects as indecomposable summands.*

Proof. Assume that T has at least one indecomposable β -object T_* as a summand (otherwise we are done). Furthermore assume that T_* is in row k of the AR-quiver of \mathcal{C} (counted from the bottom) such that there are no β -object summands of T in any row above it, and consider the following figure of T_*^\perp :

T_*^\perp is equivalent to $\mathcal{C}_{k-1} \times \mathcal{C}'$ where \mathcal{C}' is the cluster category of type \mathbb{D}_{k-1} , \mathbb{A}_3 or $\mathbb{A}_1 \times \mathbb{A}_1$. The part of \mathcal{C}' that is not directly above T_* is equivalent to a triangle of order $n - k - 2$. This follows from the well-known structure of the derived category of type \mathbb{D}_n (for instance, one can use the “knitting” technique to see this). But this means that T can have at most $k - 1$ summands in the subcategory equivalent to \mathcal{C}_{k-1} , and at most $n - k - 2$ summands that are β -objects in \mathcal{C}' since no summands can be directly above T_* . Hence there are at most $1 + k - 1 + n - k - 2 = n - 2$ β -objects in total, and so there must be at least 2 α -objects. \square

We now describe how the indecomposable summands of a cluster-tilting object are distributed in the cluster category. We show how different choices of α -objects give rise to the different types of cluster-tilted algebras. The way we group the α -objects is as follows:

- (a) some α -object A and ϕA ,
- (b) two α -objects A and A' such that $A' \neq \phi A$, or
- (c) three or more α -objects.

In the following lemmas we assume that T is a cluster-tilting object in \mathcal{C} inducing a cluster-tilted algebra $B = \text{End}(T)^{\text{op}}$ with quiver Q_B . We also assume that the decomposition $T = T_1 \oplus T_2$ is the decomposition from Corollary 3.6.

Lemma 4.3. *If $T_1 = A \oplus \phi A$, then Q_B is of the following type:*

where the \star -vertices are connecting vertices of possibly empty \mathbb{A} -triangles.

Proof. We know that A^\perp is equivalent to \mathcal{C}_{n-1} . We also know that ϕA is an object in the outmost τ -orbit of A^\perp , and thus can be considered equivalent to the object induced by the projective-injective module for some embedding of $\text{mod } kQ_{n-1}$ in A^\perp , which in particular is $\phi A \cup \mathcal{B}$. Thus ϕA corresponds to a connecting vertex $\bullet_{\phi A}$ in an \mathbb{A} -triangle Q' .

If there is exactly one arrow going into or out of $\bullet_{\phi A}$, the vertex this arrow comes from (or goes to) is again a connecting vertex \star for the subquiver $Q' \setminus \bullet_{\phi A}$. It is easy to see from the definition of an \mathbb{A} -triangle that $Q' \setminus \bullet_{\phi A}$ is again an \mathbb{A} -triangle. Furthermore, since $\text{Hom}_{\mathcal{C}}(X, A) = \text{Hom}_{\mathcal{C}}(X, \phi A)$ and $\text{Hom}_{\mathcal{C}}(A, Y) = \text{Hom}_{\mathcal{C}}(\phi A, Y)$ for all $X, Y \in \mathcal{C}$, we see that Q is of the desired type but with one empty \mathbb{A} -triangle.

If $\bullet_{\phi A}$ is a vertex with exactly one arrow going into it and one going out of it in some 3-cycle, it is easy to see that $Q' \setminus \bullet_{\phi A}$ is two \mathbb{A} -triangles connected by the remaining arrow of the previous 3-cycle. By the same Hom-argument as in the previous paragraph we can add a vertex corresponding to A which is part of a 3-cycle sharing one arrow with the 3-cycle of A' (since any map factoring through A' factors through A). Thus Q is of the desired type and without empty \mathbb{A} -triangles. \square

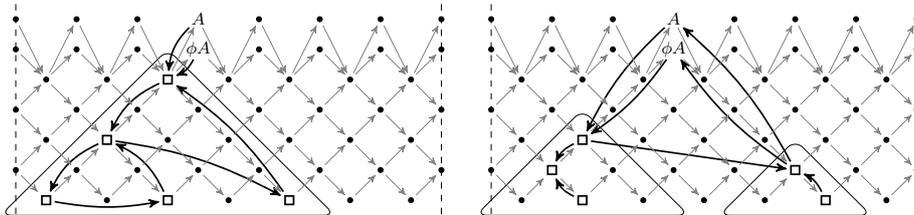

Figure 4.1: Diagrams of cluster-tilting objects as in Lemma 4.3.

Lemma 4.4. *If $T_1 = A \oplus A'$ such that A' is different from ϕA , then Q_B is of the following type:*

where the \star -vertices are connecting vertices of possibly empty \mathbb{A} -triangles.

Proof. We are in the setup of Lemma 3.9. Note that if $A' = \tau^\pm \phi A$ then one of the Δ 's is empty. The claim now follows from Corollary 3.4. \square

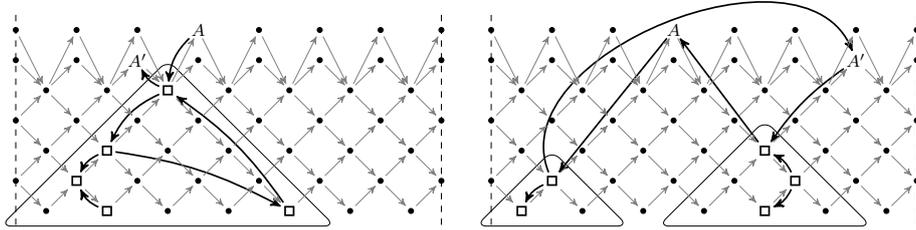

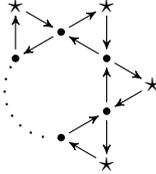

Figure 4.2: Diagrams of cluster-tilting objects as in Lemma 4.4. In the left example, one triangle is empty, and hence disappears.

Lemma 4.5. *If $T_1 = A_1 \oplus A_2 \oplus \dots \oplus A_n$ where $n \geq 3$, then Q_B is of the following type:*

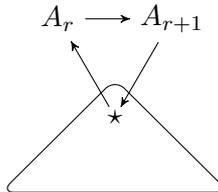

where the \star -vertices are connecting vertices of possibly empty \mathbb{A} -triangles.

Proof. Assume that $T_1 = A_1 \oplus A_2 \oplus \dots \oplus A_n$ where $n \geq 3$, and that $A_t = \tau^{-st} A_1$ or $\tau^{-st}(\phi A_1)$ for $2 \leq t \leq n$. Then $\bigcap_{1 \leq s \leq t} \mathcal{B}(A_s)$ is a union of n disjoint, possibly empty, triangles in $\mathcal{B}(A_1)$ by Lemma 3.9. If $A_i = \tau^{-1}(\phi A_{i+1})$ for some i , the corresponding triangle is empty. In particular there will be an n -cycle

$$A_1 \rightarrow A_2 \rightarrow A_3 \rightarrow \dots \rightarrow A_n \rightarrow A_1$$

where the arrow $A_r \rightarrow A_{r+1}$ has a triangle of order $k-1$ "attached" if $A_{r+1} = \tau^{-k} A_r$:

The relations also follow from Lemma 3.9. Now we are done by Corollary 3.4. \square

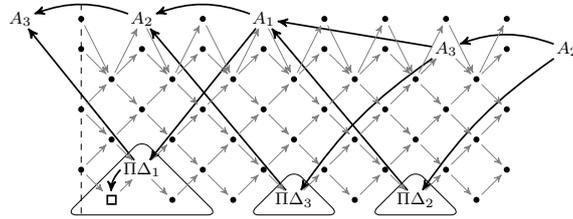

Figure 4.3: Diagram of a cluster-tilting object as in Lemma 4.5.

This finishes the proof of Theorem 4.1. Also note that we obtained a new proof of the main result of [15].

Remark. The cluster category of type \mathbb{D}_n has also been modeled geometrically as a polygon with n vertices and a puncture in its center in [13]. Here the cluster-tilting objects correspond to triangulations of the polygon. Some results in this subsection could be proved using this approach. One can, for instance, derive Lemma 4.2 from the fact that the α -objects correspond to arcs in the punctured polygon that are incident to the puncture. Every triangulation contains at least two arcs incident to the puncture and thus every cluster tilting object has at least two α -objects as summands¹.
