Computation of the Largest Constraint Admissible Set for Linear Continuous-Time Systems with State and Input Constraints

Moritz Schulze Darup * Martin Mönnigmann *

* Automatic Control and Systems Theory, Ruhr-Universität Bochum, Bochum, Germany. (e-mail: moritz.schulzedarup@rub.de)

Abstract: We present a new method for the approximation of the largest constraint admissible set (CAS) for linear continuous-time systems with state and input constraints. The CAS is the set of initial states for which the controlled system does not violate the input or state constraints. The presented approach is based on a suitable discretization of the continuous-time system. In fact, we will show that CAS in the continuous-time case can be computed analogously to the discrete-time case, given an appropriate sampling time was chosen. We stress that the computation of CAS for continuous-time systems is considerably more difficult than for discrete-time systems, since one has to guarantee that the system does not violate the constraints in between the sampling instances.

Keywords: linear continuous-time systems, constraints, terminal control, predictive control

1. INTRODUCTION

Constraint admissible sets (CAS) are important for the analysis of controlled systems with constraints. The CAS is defined to be the set of initial conditions \( x_0 \) for which the closed-loop trajectory emanating from \( x_0 \) does not violate the input and state constraints (see, e.g., Gilbert and Tan (1991) or Wang et al. (2009)). CAS are of special interest in the framework of constrained linear quadratic regulation (Scokaert and Rawlings, 1998) or model predictive control (MPC). In fact, CAS are instrumental for the analysis of controlled systems with constraints. The CASs guarantee (asymptotic) stability of the controlled system, an outer approximation of the largest CAS (denoted by \( \mathbb{C}^\infty \)) can be found by discretizing the system and computing \( \hat{\mathbb{C}}^\infty \) for the resulting discrete-time system (Gilbert and Tan, 1991). Unfortunately, outer approximations \( \mathbb{C}^\infty \supseteq \mathbb{C}^\infty \) of tight inner approximations \( \mathbb{C}^\infty \) of \( \mathbb{C}^\infty \) are of little use, since they may contain \( \mathbb{C} \) for which the closed-loop trajectory emanating from \( x_0 \) violates the input or state constraints. Here, we intend to derive a method for the computation of tight inner approximations \( \mathbb{C}^\infty \) of \( \mathbb{C}^\infty \). Precisely, for any given \( \epsilon \in (0, 1) \), we show how to compute a set \( \mathbb{C}^\infty \) such that

\[
\mathbb{C}^\infty \subseteq \mathbb{C}^\infty \quad \text{and} \quad (1 - \epsilon) \mathbb{C}^\infty \subseteq \mathbb{C}^\infty.
\]

Essentially, we provide a criterion for an appropriate choice of the sampling time (see Eq. (29)).

The paper is organized as follows. We introduce some notation and preliminaries in the remainder of this section. Afterwards, we recall how to calculate the largest CAS for constrained discrete-time systems in the first part of Sect. 2. We extend the established results by providing an upper bound for the number of iterations necessary to identify \( \mathbb{C}^\infty \). The main result of the paper, i.e., the computation of a tight inner approximation of \( \mathbb{C}^\infty \), is presented in Sect. 3. Finally, we analyze two numerical examples and state conclusions in Sects. 4 and 5, respectively.

1.1 Preliminaries and Notation

We denote matrices by capital letters, vectors and scalars by lowercase letters and sets by calligraphic letters. Let \( A, P \in \mathbb{R}^{n\times n} \) and \( B \in \mathbb{R}^{n\times m} \) with \( P = P^T \) and \( n, m \in \mathbb{N} \). By \( \|A\|_2 \) and \( \mu_2(A) \) denote the spectral norm and the associated logarithmic norm (see Söderlind (2006)) of \( A \). By \( \lambda_{\min}(P) \) and \( \lambda_{\max}(P) \) denote the smallest and the largest eigenvalue of the (symmetric) matrix \( P \), respectively. By \( B(r) := \{ x \in \mathbb{R}^n | \| x \|_2 \leq r \} \), denote a ball in \( \mathbb{R}^n \) with radius \( r \in \mathbb{R}_+ \), where \( \mathbb{R}_+ := \{ r \in \mathbb{R} | r > 0 \} \). Let \( \mathcal{E}(r) := \{ x \in \mathbb{R}^n | \| x \|_2^2 \leq r^2 \} \) be shorthand notation for an ellipsoid, where \( \| x \|_P^2 := x^T P x \) and where \( P \in \mathbb{R}^{n\times n} \). Define \( \mathcal{N}_r := \{ r \in \mathbb{R} | r \geq 0 \} \). Let \( \mathcal{N}_{ij} := \{ i \in \mathbb{N} | j \leq i \} \) and \( \mathcal{N}_{ij,k} := \{ i \in \mathbb{N} | j \leq i \leq k \} \). Finally, let \( \mathcal{T} \subseteq \mathbb{R}^n \) and \( \lambda \in (0, 1) \) and define \( \mathcal{T}^\lambda := \lambda \mathcal{T} := \{ \lambda x | x \in \mathcal{T} \} \). The set \( \mathcal{T} \) is called \( A \)-invariant, if \( A x \in \mathcal{T} \) for every \( x \in \mathcal{T} \). The following lemmas summarize some properties which we use in later sections.

Lemma 1. Let \( \mathcal{T} \subseteq \mathbb{R}^n \) be \( A \)-invariant and let \( \epsilon \in (0, 1) \).

Then, (i) \( (1 - \epsilon) \mathcal{T} \) is \( A \)-invariant and (ii) \( A^k x \in \mathcal{T} \) for every \( x \in \mathcal{T} \) and every \( k \in \mathbb{N} \).

* This research was partly funded by the Deutsche Forschungsgemeinschaft (DFG, MO 1086/11-1).
Lemma 2. Let \( \mathcal{T} \subset \mathbb{R}^n \) be a convex and compact set with \( 0 \in \text{int}(\mathcal{T}) \), let \( \epsilon \in (0,1) \) and let \( \mathcal{U} \subset \mathbb{R}_+ \) be such that \( \mathcal{B}(\epsilon) \subseteq \mathcal{T} \). Let \( x \in (1-\epsilon) \mathcal{T} \) and let \( \Delta x \in \mathbb{R}^n \). If \( \|\Delta x\|_2 \leq \epsilon x \), then \( x + \Delta x \in \mathcal{T} \).

2. THE DISCRETE-TIME CASE

In this section, we consider discrete-time linear systems
\[
\dot{x}(k+1) = \bar{A} \dot{x}(k) + \bar{B} \hat{u}(k), \quad \dot{x}(0) = x_0
\]
with input and state constraints of the form
\[
\hat{u}(k) \in \bar{U} \quad \text{and} \quad \dot{x}(k) \in \bar{X} \quad \text{for every} \ k \in \mathbb{N},
\]
where \( \bar{A} \in \mathbb{R}^{n \times n} \) and \( \bar{B} \in \mathbb{R}^{n \times m} \) and where \( \bar{U} \subset \mathbb{R}^m \) and \( \bar{X} \subset \mathbb{R}^n \) are assumed to be convex and compact sets with the origin as an interior point. We further assume that a linear control law
\[
\hat{u}(k) = -\bar{K} \dot{x}(k)
\]
with \( \bar{K} \in \mathbb{R}^{n \times m} \) is given, such that the closed-loop system
\[
\dot{x}(k+1) = (\bar{A} - \bar{B} \bar{K}) \dot{x}(k), \quad \dot{x}(0) = x_0
\]
is Schur stable. In the following, we recall the procedure for the computation of the largest CAS in the discrete-time case. In order to clearly divide between established results and new findings, we introduce the subsections State of the art and Improvement (here and in Sect. 3).

2.1 State of the art: Exact computation of \( \hat{C}_\infty \)

Let \( \hat{\varphi}(k, x_0) \) denote the solution of the closed-loop system (5) at step \( k \in \mathbb{N} \) for initial condition \( x_0 \) and define the set
\[
\hat{C}_{\max} := \{ \hat{x} \in \bar{X} \mid -\bar{K} \hat{x} \in \bar{U} \},
\]
which collects all states \( \hat{x} \in \bar{X} \) for which the application of the feedback law (4) does not violate the inputs constraints \( \mathcal{U} \). Then, the largest CAS \( \hat{C}_\infty \) can be expressed as (Gilbert and Tan, 1991)
\[
\hat{C}_\infty := \{ x_0 \in \hat{C}_{\max} \mid \hat{\varphi}(k, x_0) \in \hat{C}_{\max}, \forall k \in \mathbb{N} \}.
\]
We collect some statements which are important for the characterization of \( \hat{C}_\infty \).

Theorem 5. Let \( i \in \mathbb{N} \). If \( \hat{C}_i = \hat{C}_{i+1} \), then \( \hat{C}_\infty = \hat{C}_i \).

2.2 Improvement: Maximal number of iterations

In order for Alg. 1 to be useful in practice, we have to guarantee that the termination criterion \( \hat{C}_i = \hat{C}_{i+1} \) is met after a finite number of iterations. In principle, Thm. 4.1 in Gilbert and Tan (1991) provides this guaranty. We extend this theorem by providing an upper bound for the number of iterations required by Alg. 1. The basic idea is to study the convergence rate of the unconstrained system to the origin. A similar approach was used in Fiaccchini et al. (2007) to compute \( \lambda \)-contractive polytopic sets for linear and nonlinear discrete-time systems. Basically, the proof of the following lemma represents a specialized variant of the proof of the well-known Lyapunov criterion for asymptotic stability (see, e.g., (Vidyasagar, 2002, pp. 165 ff.)). As a preparation, note that, for every positive definite matrix \( \hat{Q} = \hat{Q}^T \), the discrete-time Lyapunov matrix equation
\[
(\bar{A} - \bar{B} \bar{K})^T \hat{P} (\bar{A} - \bar{B} \bar{K}) - \hat{P} + \hat{Q} = 0
\]
has a unique solution for \( \hat{P} = \hat{P}^T \) and this solution is positive definite since \( (\bar{A} - \bar{B} \bar{K}) \) is Schur stable by assumption (see, e.g., (Vidyasagar, 2002, p. 267)).

Lemma 6. Let \( \hat{Q} = \hat{Q}^T \geq 0 \) be arbitrary and let \( \hat{P} = \hat{P}^T \geq 0 \) be the solution of (10). Let \( \rho, \hat{\rho} \in \mathbb{R}_+ \) with \( \rho \leq \hat{\rho} \) and let \( \rho \in \mathcal{E}(\hat{\rho}, \hat{\rho}) \). Then, \( \hat{\varphi}(k, x_0) \in \mathcal{E}(\hat{\rho}, \rho) \) for every \( k \in \mathbb{N} \) with \( k \geq t_{\max} \), where
\[
t_{\max} := (\rho^2 - \hat{\rho}^2) + \frac{\lambda_{\max}(\hat{P})}{\lambda_{\min}(\hat{Q})}.
\]

Proof. We first show that \( \hat{x}_0 \in \mathcal{E}(\hat{\rho}, \rho) \) implies \( \hat{\varphi}(i, x_0) \in \mathcal{E}(\hat{\rho}, \rho) \) for at least one \( i \in \mathbb{N}_{0, t_{\max}} \). If \( \hat{x}_0 \in \mathcal{E}(\hat{\rho}, \rho) \), then \( \hat{\varphi}(i, x_0) \in \mathcal{E}(\hat{\rho}, \rho) \) for every \( i \in \mathbb{N}_{0, t_{\max}} \). Let \( \hat{\varphi}(i, x_0) \in \mathcal{E}(\hat{\rho}, \rho) \) for every \( i \in \mathbb{N}_{0, t_{\max}} \). Let the positive definite function \( \hat{v}(x) = \|x\|_\rho^2 \) and note that
\[
\hat{v}(x) \leq \hat{\rho}^2 \quad \iff \quad x \in \mathcal{E}(\hat{\rho}, \rho).
\]

It follows from (10), that the trajectories of the closed-loop system (5) satisfy the relation
\[
\Delta \hat{v}(k, x_0) = -\|\hat{\varphi}(k, x_0)\|_\rho^2
\]
for every \( \hat{x}_0 \in \mathbb{R}^n \) and every \( k \in \mathbb{N} \), where \( \Delta \hat{v}(k, x_0) := \hat{v}(\hat{\varphi}(k+1, x_0)) - \hat{v}(\hat{\varphi}(k, x_0)) \). In the remainder of the proof, we use (13) to show
\[
\|\hat{\varphi}(i_{\max}, x_0)\|_\rho^2 < \hat{\rho}^2,
\]
which results in the desired contradiction, since (14) implies \( \hat{\varphi}(i_{\max}, x_0) \in \mathcal{E}(\hat{\rho}, \rho) \) with (12). To show (14), first note that
\[
\|\hat{\varphi}(i_{\max}, x_0)\|_\rho^2 = \hat{v}(x_0) + \sum_{k=0}^{i_{\max}} \Delta \hat{v}(k, x_0)
\]
for every $i \in \mathbb{N}$. Thus, overestimating the l.h.s. in (14) yields
\[
\dot{\hat{v}}(\hat{\phi}(i_{\text{max}}, \hat{x}_0)) = \hat{v}(\hat{x}_0) - \sum_{k=0}^{i_{\text{max}}-1} \|\hat{\phi}(k, \hat{x}_0)\|^2_P,
\]
where the first relation holds according to (15) and (13). To understand the second and the third relation, first note that $\hat{v}(\hat{x}_0) \leq \hat{\mathbf{p}}^2$ according to (12) since $\hat{x}_0 \in \mathcal{E}(P, \mathbf{p})$ by assumption. Moreover, we have
\[
\lambda_{\text{min}}(V) \|\hat{x}\|^2 \leq \|\hat{v}\|^2 \leq \lambda_{\text{max}}(V) \|\hat{x}\|^2
\]
for any symmetric matrix $V \in \mathbb{R}^{n \times n}$ (Horn and Johnson, 1985, p. 176). Thus, we obtain the second and the third relation, since $Q$ and $P$ are symmetric positive definite matrices. The fourth relation results with the assumption that $\hat{v}(i, \hat{x}_0) \notin \mathcal{E}(P, \mathbf{p})$ for every $i \in \mathbb{N}_{0, i_{\text{max}}}^+$, i.e.,
\[
\dot{\hat{v}}(i, \hat{x}_0) = \|\hat{\phi}(i, \hat{x}_0)\|^2_P > \hat{\mathbf{p}}^2
\]
according to (12). Finally, the fifth and the sixth relation hold due to $i_{\text{max}} \geq t_{\text{max}}$ and by definition of $t_{\text{max}}$ in (11). In summary, we obtain (14). Thus, we proved that there exists an $i^* \in \mathbb{N}_{0, i_{\text{max}}}$ such that $\hat{v}(i^*, \hat{x}_0) \notin \mathcal{E}(\hat{P}, \hat{\mathbf{p}})$. Taking into account that $\Delta \hat{v}(k, \hat{x}_0) \leq 0$ for every $k \in \mathbb{N}$ and every $\hat{x}_0 \in \mathbb{R}^n$, it directly follows from (15) that $\hat{v}(i^*, \hat{x}_0) \in \mathcal{E}(\hat{P}, \hat{\mathbf{p}})$ implies $\hat{v}(k, \hat{x}_0) \in \mathcal{E}(\hat{P}, \hat{\mathbf{p}})$ for every $k \in \mathbb{N}_{i^*}$.

It is obvious how to apply Lem. 6 in order to provide the desired iteration bound. Basically, the ellipsoids $\mathcal{E}(\hat{P}, \hat{\mathbf{p}})$ and $\mathcal{E}(\hat{P}, \hat{\mathbf{p}})$ should be chosen in such a way that they approximate the set $\hat{C}_{\text{max}}$ from inside and outside, respectively. Proposition 7 formalizes this approach. See the discrete-time example in Sect. 4.1 for a geometrical interpretation.

Proposition 7. Let $\hat{Q} = \hat{Q}^T > 0$ be arbitrary and let $\hat{P} = \hat{P}^T > 0$ be the solution of (10). Let $\hat{P}, \mathbf{p} \in \mathbb{R}^n_+$ be such that $\mathcal{E}(\hat{P}, \hat{\mathbf{p}}) \subseteq \hat{C}_{\text{max}} \subseteq \mathcal{E}(\hat{P}, \hat{\mathbf{p}})$ and let $t_{\text{max}}$ be defined as in (11). Then, there exists an $i \in \mathbb{N}$ with $i < t_{\text{max}}$ such that $\hat{C}_i = \hat{C}_{i+1}$, where $i_{\text{max}} := \max\{t_{\text{max}}, 1\}$.

Proof. Since $\hat{C}_{\text{max}} \subseteq \mathcal{E}(\hat{P}, \hat{\mathbf{p}})$, we have $\hat{v}(k, \hat{x}_0) \in \mathcal{E}(\hat{P}, \hat{\mathbf{p}}) \subseteq \hat{C}_{\text{max}}$ for every $\hat{x}_0 \in \hat{C}_{\text{max}}$ and every $k \in \mathbb{N}_{i_{\text{max}}}$ according to Lem. 6. In particular, we find $\hat{v}(i_{\text{max}}, \hat{x}_0) \in \hat{C}_{\text{max}}$ for every $\hat{x}_0 \in \hat{C}_{\text{max}}$. Thus, we obtain
\[
\hat{x}_0 \in \hat{C}_{i_{\text{max}}-1} \implies \hat{x}_0 \in \hat{C}_{i_{\text{max}}-1}
\]
according to the definition of $\hat{C}_i$ in (8). Obviously, $i_{\text{max}}$ implies $\hat{C}_{i_{\text{max}}-1} \subseteq \hat{C}_{\text{max}}$. Since we also have $\hat{C}_{i_{\text{max}}-1} \subseteq \hat{C}_{\text{max}}$ according to (9), we finally find $\hat{C}_{i_{\text{max}}-1} = \hat{C}_{\text{max}}$. Thus, there exists at least one $i \in \mathbb{N}$ with $i < i_{\text{max}}$ such that $\hat{C}_i = \hat{C}_{i+1}$, e.g., $i = i_{\text{max}} - 1$.

Note that it is necessary to use $i_{\text{max}} := \max\{t_{\text{max}}, 1\}$ in Prop. 7 in order to guarantee $i_{\text{max}} \geq 1$ for the (rare but possible) exception $t_{\text{max}} = 0$.

3. THE CONTINUOUS-TIME CASE
Consider the continuous-time linear system
\[
\dot{x}(t) = A x(t) + B u(t), \quad x(0) = x_0
\]
with input and state constraints of the form
\[
u(t) \in \mathcal{U} \quad \text{and} \quad x(t) \in \mathcal{X} \quad \text{for every } t \in \mathbb{R}_0.
\]
Further assume that a linear control law
\[
u(t) = -K x(t)
\]
is given, such that the closed-loop system
\[
\dot{x}(t) = (A - BK)x(t), \quad x(0) = x_0
\]
is Hurwitz stable.

3.1 State of the art: Outer approximation of $C_{\text{C}}$
Let $\phi(t, x_0)$ denote the solution of the closed-loop system (21) at time $t \in \mathbb{R}_0$ with initial condition $x_0$ and define the set
\[
C_{\text{C}} := \{x \in \mathcal{X} \mid -K x \in \mathcal{U}\}.
\]
Then, analogously to the discrete-time case, the largest CAS for continuous-time systems can be expressed as
\[
C_{\infty} := \{x_0 \in C_{\text{C}} \mid \phi(t, x_0) \in C_{\text{C}}, \forall t \in \mathbb{R}_0\}.
\]
Inspired by (8), we may overestimate $C_{\infty}$ by considering only a finite number of points in time. Let
\[
C_{\Delta t} := \{x_0 \in C_{\text{C}} \mid \phi(k \Delta t, x_0) \in C_{\text{C}}, \forall k \in \mathbb{N}_{0, i}\}
\]
for an arbitrary but fixed $\Delta t \in \mathbb{R}_+$ and note that
\[
C_{\infty} \subseteq C_{\Delta t} \subseteq C_{\Delta t} \subseteq C_{\text{C}}
\]
for every $i \in \mathbb{N}$. With regard to (24), the computation of $C_{\Delta t}$ builds on the discretization of the continuous-time system based on the sample time $\Delta t$. To see this, note that $\phi(k \Delta t, x_0)$ can be written as
\[
\phi(k \Delta t, x_0) = \exp((A - BK)k \Delta t) x_0.
\]
Obviously, the outer approximation of $C_{\infty}$ in terms of $C_{\Delta t}$ generally becomes “tighter” for larger $i \in \mathbb{N}$ and smaller $\Delta t \in \mathbb{R}_+$, respectively. However, in contrast to the discrete-time case, the limit
\[
C_{\infty} := \lim_{i \to \infty} C_{\Delta t}
\]
is, in general, still an overestimation of the largest CAS, i.e., $C_{\infty} \subseteq C_{\infty}$. This is due to the fact that $C_{\Delta t}$ is generally not positively invariant\(^1\) for system (21). To solve this problem, it is reasonable to scale $C_{\Delta t}$ in such a way that the shrunken set is a subset of $C_{\infty}$. Obviously, the underlying scaling factor determines the accuracy of the inner approximation. Thus, if we are interested in a certain user-defined accuracy (see $\epsilon$ in (1)), the scaling is limited. We have to choose the remaining parameter $\Delta t$ in an appropriate way to address these limitations. In fact, Gilbert and Tan (1991) already showed that an appropriate $\Delta t$ always exists. We summarize the corresponding result in the following theorem which builds on (Gilbert and Tan, 1991, Thm. 6.1).

Theorem 8. For every $\epsilon \in (0, 1)$ there exists a $\Delta t \in \mathbb{R}_+$ such that
\[
(1 - \epsilon) C_{\Delta t} \subseteq C_{\infty} \subseteq C_{\Delta t}.
\]
\(^1\) For discrete-time systems, a $(A - BK)\Delta t$-invariant set $T$ is also positively invariant for the closed-loop system (5). In contrast, for continuous-time systems, a $\exp((A - BK)\Delta t)$-invariant set $T$ is not necessarily positively invariant for (21). See (Blanchini and Miani, 2008, p. 99 ff.) or Blanco and De Moor (2007) for details on positive invariance.
3.2 Improvement: Appropriate discretization

In principle, Thm. 8 provides the statement that we are looking for. Assume we found a $\Delta t \in \mathbb{R}_+$ such that (27) holds for a given $\epsilon \in (0, 1)$, then the choice $C_{\infty} = (1 - \epsilon) C_{\infty}^d$ fulfills (1). To see this, note that $C_{\infty} = (1 - \epsilon) C_{\infty}^d \subseteq C_{\infty}^d$. Moreover, multiplying the second relation in (27) with the factor $(1 - \epsilon) > 0$ yields

$$(1 - \epsilon) C_{\infty} \subseteq (1 - \epsilon) C_{\infty}^d = C_{\infty}.$$  

Note that, analogously to the discrete-time case, the set $C_{\infty}^d$ can be exactly calculated by a finite number of iterations (see Prop. 15 further below for details). Thus, it only remains to choose $\Delta t \in \mathbb{R}_+$. Unfortunately, neither Thm. 8 nor the corresponding proof in Gilbert and Tan (1991) provide a practical algorithm for the computation of $\Delta t$. The main contribution of this paper is a simple criterion (see Eq. (29)) for an appropriate choice of $\Delta t$ such that (27) (or equivalently (1) with $C_{\infty} = (1 - \epsilon) C_{\infty}^d$) holds. This criterion will be used to provide a method for the tight inner approximation of $C_{\infty}$, which is summarized in Prop. 12. Several steps are required as a preparation to Prop. 12. We begin by formulating conditions on a set $T$ to be a subset of the largest CAS.

Obviously, the following lemma represents the continuous-time counterpart to Lem. 3.

**Lemma 9.** Let $\Delta t \in \mathbb{R}_+$ and let $T \subseteq C_{\infty}$ be $A$-invariant with $A = \exp((A - BK \Delta t) t)$. Let $\phi(\tau, x_0)$ be in $C_{\infty}$ for every $x_0 \in T$ and every $\tau \in [0, \Delta t]$. Then $T \subseteq C_{\infty}$.

**Proof.** We have to show that $\phi(\tau, x_0) \in C_{\infty}$ for every $x_0 \in T$ and every $t \in \mathbb{R}_0$. Since $T$ is $A$-invariant, we have $\exp((A - BK) (k - 1) / \Delta t) x_0 = \phi(k \Delta t, x_0) \in T$ for every $x_0 \in T$ and $k \in \mathbb{N}$ according to Lem. 1. Moreover, we have $\phi(\tau, x_0) \in C_{\infty}$ for every $x_0 \in T$ and every $\tau \in [0, \Delta t]$ by assumption. Thus, since $\phi(k \Delta t, x_0) \in C_{\infty}$, we obtain

$$\phi(\tau, \phi(k \Delta t, x_0)) = \phi(k \Delta t + \tau, x_0) \in C_{\infty} \quad (28)$$

for every $x_0 \in T$, every $k \in \mathbb{N}$ and every $\tau \in [0, \Delta t]$. Now let $x_0 \in T$ and $t \in \mathbb{R}_0$ be arbitrary but fixed. Set $k^* = \lceil \frac{t}{\Delta t} \rceil$ and $\tau^* = t - k^* \Delta t$ and note that $k^* \in \mathbb{N}$, $\tau^* \in [0, \Delta t)$ and $t = k^* \Delta t + \tau^*$. Thus

$$\phi(t, x_0) = \phi(k^* \Delta t + \tau^*, x_0) \in C_{\infty}$$

according to (28). This completes the proof, since $x_0 \in T$ and $t \in \mathbb{R}_0$ were arbitrary.

Similar to the discrete-time blueprint, Lem. 9 requires $T$ to be $A$-invariant (with $A = \exp((A - BK \Delta t) t)$). Analogously to Lem. 4, $C_{\infty}^\Delta t = C_{\infty}^{\Delta t}$ implies $A$-invariance. This is summarized in the following lemma.

**Lemma 10.** If $C_{\infty}^{\Delta t} = C_{\infty}^{\Delta t}$, then $C_{\infty}^{\Delta t}$ is $A$-invariant with $A = \exp((A - BK \Delta t) t)$.

We omit the proof of Lem. 10 since it is a direct consequence of Lem. 4. While Lem. 3 (discrete-time) and Lem. 9 (continuous-time) are similar in terms of $A$-invariance, Lem. 9 differs from Lem. 3 in that it contains additional conditions on $\phi(\tau, x_0)$. A simple criterion for the fulfillment of these conditions is introduced in Lem. 11.

**Lemma 11.** Let $\epsilon \in (0, 1)$ and let $T$ be such that $T \subseteq (1 - \epsilon) C_{\infty}$ Max. Let $\mathbb{R}_+^\tau \in \mathbb{R}_+$ be such that $B(\tau) \subseteq C_{\infty}$ and $T \subseteq B(\tau)$. Finally, let $\Delta t \in \mathbb{R}_+$ be such that

$$\Delta t \leq \frac{1}{\mu_2(A - BK)} \ln \left( \frac{\mu_2(A - BK) \epsilon T}{\|A - BK\|_2} + 1 \right).$$

(29)

Then, $\phi(\tau, x_0) \in C_{\infty}$ for every $x_0 \in T$ and $\tau \in [0, \Delta t)$.

**Proof.** Assume for a moment

$$\|\phi(\tau, x_0) - x_0\|_2 \leq \epsilon$$

for every $x_0 \in T$ and every $\tau \in [0, \Delta t)$. Define $\Delta x(\tau, x_0) := \phi(\tau, x_0) - x_0$. Then, we have

$$\phi(\tau, x_0) = x_0 + \Delta x(\tau, x_0) = x_0 + \Delta x(\tau, x_0) \in C_{\infty}$$

for every $x_0 \in T \subseteq (1 - \epsilon) C_{\infty}$ and every $\tau \in [0, \Delta t)$ according to Lem. 2 in combination with (30) and $B(\tau) \subseteq C_{\infty}$. Thus, it remains to show (30) in order to prove the claim in Lem. 11. To do so, we initially note that the l.h.s. in (30) cannot be larger than the arc length

$s(\tau, x_0) = \int_0^\tau \|\dot{\phi}(t, x_0)\|_2 dt$ (31)

at time $\tau$ of the trajectory emanating from $x_0$. Thus, we have

$$\|\phi(\tau, x_0) - x_0\|_2 \leq s(\tau, x_0)$$

for every $x_0 \in T$ and every $\tau \in [0, \Delta t)$. Since $\phi(\tau, x_0)$ refers to the solution of (21), the derivative of the trajectory with respect to $t$ is given by

$$\dot{\phi}(t, x_0) = (A - BK) \phi(t, x_0),$$

(32)

Overestimating the arc length (31) yields

$$s(\tau, x_0) = \int_0^\tau \|\dot{\phi}(t, x_0)\|_2 dt \leq \int_0^\tau \|A - BK\|_2 \|\phi(t, x_0)\|_2 dt = \frac{\mu_2(A - BK) \epsilon T}{\|A - BK\|_2} \int_0^\tau \|\phi(t, x_0)\|_2 dt \leq \frac{\mu_2(A - BK) \epsilon T}{\|A - BK\|_2}$$(33)

and (30) is indeed fulfilled.

The combination of Lem. 9, 10 and 11 leads to Prop. 12, which states a method for the tight underestimation of $C_{\infty}$ based on an appropriate discretization in terms of $\Delta t$.

**Proposition 12.** Let $\epsilon \in (0, 1)$ and let $C_{\infty}^{\Delta t} \in \mathbb{R}_+$ be such that $B(\tau) \subseteq C_{\infty}$ and $(1 - \epsilon) C_{\infty} \subseteq B(\tau)$. Let $t \in \mathbb{N}$ and let $\Delta t \in \mathbb{R}_+$ be such that (29) holds. If $C_{\infty}^{\Delta t} = C_{\infty}^{\Delta t}$, then $C_{\infty}^{\Delta t}$ is such that (1) holds.

**Proof.** In order to prove the claim, we assume $C_{\infty}^{\Delta t} = C_{\infty}^{\Delta t}$ and show that the relations (1) are fulfilled for the choice $C_{\infty}^{\Delta t} = (1 - \epsilon) C_{\infty}^{\Delta t}$. The second relation in (1) obviously holds, since we have
In order to prove the first relation in (1), i.e., \( \mathcal{C}_\infty \subseteq \mathcal{C}_\Delta t \), we will apply Lem. 9. It remains to show that \( \mathcal{C}_\infty \) is \( \tilde{A} \)-invariant with \( \tilde{A} = \exp((A-BK) \Delta t) \) and that \( \varphi(t, x_0) \) for every \( x_0 \in \mathcal{C}_\infty \) and \( t \in [0, \Delta t] \).

Since \( \mathcal{C}_\Delta t = \mathcal{C}_{\Delta t+1} \), it follows that \( \mathcal{C}_\Delta t \) is \( \tilde{A} \)-invariant according to Lem. 10. Thus, \( \mathcal{C}_\infty := (1-\epsilon)\mathcal{C}_\Delta t \) is \( \tilde{A} \)-invariant according to Lem. 1. In order to show (33), first note that \( \mathcal{C}_\infty = (1-\epsilon)\mathcal{C}_\Delta t \subseteq (1-\epsilon)\mathcal{C}_\max \subseteq B(\mathcal{T}) \) by definition of \( \mathcal{C}_\infty \), according to (25) and by assumption of Prop. 12, respectively. Moreover, again by assumption, we have \( B(x) \subseteq \mathcal{C}_\max \) and \( \Delta t \in \mathbb{R}_+ \) such that (29) holds. Thus, (33) follows from Lem. 11, which completes the proof.

Proposition 12 suggests to implement the following algorithm for the iterative computation of \( \mathcal{C}_\infty \):

**Algorithm 2.** Inner approximation of \( \mathcal{C}_\infty \) for \( \epsilon \in (0,1) \).

1. Choose \( \mathcal{C}, \mathcal{T} \) and \( \Delta t \) according to Prop. 12.
2. Set \( i = 0 \) and \( \mathcal{C}_\Delta t = \mathcal{C}_\max \).
3. Compute \( \mathcal{C}_\Delta t+1 \).
4. If \( \mathcal{C}_\Delta t = \mathcal{C}_\Delta t+1 \), return \( \mathcal{C}_\infty := (1-\epsilon)\mathcal{C}_\Delta t \) and terminate, otherwise increase \( i \) by one and go to step 3.

The termination of Alg. 2 after a finite number of iterations can be guaranteed analogously to the discrete-time case. In fact, we find Lem. 13 and Prop. 14 as direct counterparts behind Lem. 6. Basically, any trajectory emanating from \( E(P, \rho) \) for the particular choice \( \rho = 0.4213 \) and \( \mathcal{T} = 2.0191 \).

Thus, corresponding to Lem. 6 and Eq. (11), we obtain \( i_{\max} = 162.3200 \). According to Prop. 7, this implies that the number of iterations required by Alg. 1 can a priori be limited above by \( i_{\max} - 1 = 161 \). In practice, for this example, Alg. 1 terminates after 3 steps. Thus, the computed iteration bound is valid but conservative.

For the choice \( \tilde{K} = (0.8831 \ 0.8811) \), the closed-loop system (5) is stable. With the weighting matrix \( Q = I \), we obtain

\[
\begin{bmatrix}
0.5334 & 2.0254 & 2.0254 & 2.6003
\end{bmatrix}
\]

as a solution of (10). Moreover, it is easy to prove and visualize in Fig. 1 that we have \( E(\tilde{P}, \rho) \subseteq \mathcal{C}_\max \subseteq E(\tilde{P}, \mathcal{T}) \) for the particular choice \( \rho = 0.4213 \) and \( \mathcal{T} = 2.0191 \).

Thus, corresponding to Lem. 6 and Eq. (11), we obtain \( i_{\max} = 162.3200 \). According to Prop. 7, this implies that the number of iterations required by Alg. 1 can a priori be limited above by \( i_{\max} - 1 = 161 \). In practice, for this example, Alg. 1 terminates after 3 steps. Thus, the computed iteration bound is valid but conservative.

4.2 Continuous-time example

We now consider the continuous-time system with the matrices

\[
\begin{bmatrix}
1.0000 & 0.2212 \\
0.0000 & 0.7788
\end{bmatrix}, \quad
\begin{bmatrix}
0.0288 \\
0.2212
\end{bmatrix}
\]

and the constraints

\[
\vec{R} = \{ \dot{x} \in \mathbb{R}^2 | |\dot{x}_1| \leq 1.5, |\dot{x}_2| \leq 0.3 \},
\]

\[
\vec{U} = \{ \dot{u} \in \mathbb{R} | |\dot{u}| \leq 0.5 \}.
\]

For the choice \( \tilde{K} = (0.8831 \ 0.8811) \), the closed-loop system (5) is stable. With the weighting matrix \( Q = I \), we obtain

\[
\begin{bmatrix}
6.5334 & 2.0254 & 2.0254 & 2.6003
\end{bmatrix}
\]

as a solution of (10). Moreover, it is easy to prove and visualize in Fig. 1 that we have \( E(\tilde{P}, \rho) \subseteq \mathcal{C}_\max \subseteq E(\tilde{P}, \mathcal{T}) \) for the particular choice \( \rho = 0.4213 \) and \( \mathcal{T} = 2.0191 \).

Thus, corresponding to Lem. 6 and Eq. (11), we obtain \( i_{\max} = 162.3200 \). According to Prop. 7, this implies that the number of iterations required by Alg. 1 can a priori be limited above by \( i_{\max} - 1 = 161 \). In practice, for this example, Alg. 1 terminates after 3 steps. Thus, the computed iteration bound is valid but conservative.

4.2 Continuous-time example

We now consider the continuous-time system with the matrices

\[
(1-\epsilon)\mathcal{C}_\infty \subseteq (1-\epsilon)\mathcal{C}_\Delta t = \mathcal{C}_\infty
\]

we study the shape of the computed (approximation of) the largest CAS. Moreover, we show that the iteration bounds introduced in Props. 7 and 14 hold.

4.1 Discrete-time example

We study the same discrete-time system as in Sznaier and Damberg (1987) with the matrices

\[
\tilde{A} = \begin{bmatrix}
1.0000 & 0.2212 \\
0.0000 & 0.7788
\end{bmatrix}, \quad \tilde{B} = \begin{bmatrix}
0.0288 \\
0.2212
\end{bmatrix}
\]

and the constraints

\[
\vec{R} = \{ \dot{x} \in \mathbb{R}^2 | |\dot{x}_1| \leq 1.5, |\dot{x}_2| \leq 0.3 \},
\]

\[
\vec{U} = \{ \dot{u} \in \mathbb{R} | |\dot{u}| \leq 0.5 \}.
\]

For the choice \( \tilde{K} = (0.8831 \ 0.8811) \), the closed-loop system (5) is stable. With the weighting matrix \( Q = I \), we obtain

\[
\begin{bmatrix}
6.5334 & 2.0254 & 2.0254 & 2.6003
\end{bmatrix}
\]

as a solution of (10). Moreover, it is easy to prove and visualize in Fig. 1 that we have \( E(\tilde{P}, \rho) \subseteq \mathcal{C}_\max \subseteq E(\tilde{P}, \mathcal{T}) \) for the particular choice \( \rho = 0.4213 \) and \( \mathcal{T} = 2.0191 \).

Thus, corresponding to Lem. 6 and Eq. (11), we obtain \( i_{\max} = 162.3200 \). According to Prop. 7, this implies that the number of iterations required by Alg. 1 can a priori be limited above by \( i_{\max} - 1 = 161 \). In practice, for this example, Alg. 1 terminates after 3 steps. Thus, the computed iteration bound is valid but conservative.
\[ A = \begin{pmatrix} -0.1 & 1.0 \\ -0.2 & 0.1 \end{pmatrix}, \quad B = \begin{pmatrix} -0.9 \\ 0.5 \end{pmatrix} \]

and the constraints
\[ X = \{ x \in \mathbb{R}^2 \mid \|x\|_\infty \leq 2 \} \text{ and } U = \{ u \in \mathbb{R} \mid |u| \leq 1 \}. \]

For the choice \( K = (\begin{pmatrix} -0.1903 & 1.7768 \end{pmatrix}) \), the closed-loop system (21) is stable. Moreover, with the following weighting matrix \( Q \), we obtain the listed matrix \( P \) as a solution of (34):
\[ Q = \begin{pmatrix} 1.0 & -0.6 \\ -0.6 & 7.0 \end{pmatrix}, \quad P = \begin{pmatrix} 1.2458 & 1.5458 \\ 1.5458 & 9.5353 \end{pmatrix}. \]

To compute an inner approximation of \( C_\infty \), we have to select the sample time \( \Delta t \) such that (29) holds. We initially compute \( r = 0.5596 \) and \( \rho = 1.9311 \) such that \( B(r) \subseteq C_{\max} \subseteq \frac{1}{\rho} B(\rho) \) (see Fig. 2). Then, according to Prop. 12, \( \Delta t = 0.0105 \) results in an appropriate discretization. In order to provide an upper bound for the number of iterations required by Alg. 2, we choose \( \rho = 1.3352 \) and \( \rho = 3.9425 \) such that \( E(P, \rho) \subseteq C_{\max} \subseteq E(P, \rho) \). Then, corresponding to Lem. 13, we obtain \( t_{\max} = 80.5430 \). According to Prop. 14, this implies that the number of iterations can be either limited to \( t_{\max} = 1 = \frac{1}{t_{\max}} - 1 = 7605 \). In practice, Alg. 2 terminates after 89 steps for this example. Again, the computed iteration bound is valid but conservative.

**Fig. 2.** Visualization of (gray), \( C_{\max} \) (yellow), \( C_{\Delta t} \) (blue) and \( C_\infty \) (green) for the continuous-time example in Sect. 4.2. The dashed and the dashed-dotted elliptic shapes refer to the ellipses \( E(P, \rho) \) and \( E(P, \rho) \), respectively. The dashed and the dashed-dotted round shapes refer to the circles \( B(\rho) \) and \( \frac{1}{\rho} B(\rho) \), respectively. The solid curve represents a trajectory of the closed-loop system (21) emanating from \( x_0 = (1.76 0.29)^T \). The red vectors visualize the slope field associated with system (21) for some points at the boundary of \( C_{\Delta t} \).

The solid curve represents a trajectory of the closed-loop system (21) emanating from \( x_0 = (1.76 0.29)^T \). The red vectors visualize the slope field associated with system (21) for some points at the boundary of \( C_{\Delta t} \).

Figure 2 illustrates the shape of the computed set \( C_{\Delta t} \) and the scaled set \( C_{\infty} = (1 - \epsilon) C_{\Delta t} \). Moreover, the slope field associated with the differential equation (21) is sketched. Based on the illustrated velocity vectors and Nagumo’s invariance theorem (see, e.g., [Blanchini and Miani, 2008, pp. 101-103]), it is immediately clear that \( C_{\Delta t} \) cannot be positively invariant. Obviously, the same conclusion holds for the scaled set \( (1 - \epsilon) C_{\Delta t} \). In fact, the illustrated trajectory temporarily leaves \( C_{\infty} \). However, based on the suitable choice of \( \Delta t \), it is guaranteed (by Prop. 12) that every trajectory that starts in \( C_{\infty} \) remains in \( C_{\Delta t} \) for all times.

5. CONCLUSION AND OUTLOOK

We presented methods for the computation of CAS for constrained linear systems. For discrete-time systems, we extended established results on the iterative computation of the largest CAS \( \hat{C}_\infty \) by providing an upper bound for the number of required iterations. Simulation studies confirm the derived bound is valid but also indicate it is conservative w.r.t. the actually required number of iterations. For continuous-time systems, we showed how to reasonably discretize the system in order to provide an inner approximation of \( C_\infty \) with a certain, user-defined accuracy. In fact, criterion (29), which allows for an appropriate choice of the sampling time \( \Delta t \), is the main result of the paper. Taking this criterion into account, CAS for continuous-time systems can be computed analogously to the discrete-time case.

We claim criterion (29) is interesting, since it allows for an a priori choice of \( \Delta t \) depending on the desired accuracy. Unfortunately, appropriate sampling times will be very small, in general. Consequently, the number of iterations that are necessary to approximate \( C_\infty \) will be high. One way to reduce the number of iterations will be to start with sampling times larger than \( \Delta t \) in order to derive coarse outer approximations of \( C_\infty \). Subsequently, the required number of steps based on the small sampling time \( \Delta t \) should be significantly smaller. Future work has to investigate such strategies.
